## Abstract

A local entropy generation analysis, for water vapor absorption in LiBr-H<sub>2</sub>O solution, is performed referring to velocity, temperature and concentration fields obtained from the numerical solution of mass and energy transport equations. The hydrodynamic description is based on Nusselt boundary layer and the actual amount of irreversibility introduced is determined for a falling film over a cooled horizontal tube inside the absorber. Results are explored in different operative conditions, in order to examine the impact of the various irreversibility sources in a wide operative range. A least irreversible solution mass flow-rate can always be identified. Furthermore, a simple and general thermodynamic analysis, carried out regarding a refrigerating and a heat boosting applications of absorption systems, makes evidence of a dimensionless group " $Q/\sigma T$ " that separates the weight of the irreversibilities and gives the way to an optimization criterion applied to the absorber in order to improve the whole system efficiency. Both equilibrium condition and sub-cooling of the solution at the inlet are considered for typical temperature and concentration of refrigerators' absorbers and heat transformers' absorbers. Results suggest the importance to work at reduced mass flow-rates

23 with a thin uniform film both for refrigerators and heat transformers. In practice, tension-active  
24 additives are required to realize this condition. Also, it is highlighted that, for a fixed operative  
25 Reynolds, the two parameters defined with reference to the dimensionless group " $Q/\sigma T$ " can be  
26 maximized by specific values of the tube radius, solution sub-cooling and temperature difference  
27 between the wall and the inlet solution.

28

## 29 Nomenclature

30	$\alpha$	Thermal diffusivity [ $\text{m}^2\text{s}^{-1}$ ]
31	$C$	Molar concentration [ $\text{mol}\cdot\text{m}^{-3}$ ]
32	$c_p$	Isobaric molar heat [ $\text{J}\cdot\text{mol}^{-1}\text{K}^{-1}$ ]
33	$D$	Mass diffusivity [ $\text{m}^2\text{s}^{-1}$ ]
34	$DA$	Dimensionless absorption flux at the interface
35	$DQ$	Dimensionless heat flux at the wall
36	$E$	Entropy generation rate per tube unit length [ $\text{W}\cdot\text{m}^{-1}\text{K}^{-1}$ ]
37	$g$	Gravity [ $\text{m}\cdot\text{s}^{-2}$ ]
38	$G$	Mass flux per unit surface [ $\text{kg}\cdot\text{m}^{-2}\text{s}^{-1}$ ]
39	$h$	Molar enthalpy [ $\text{J}\cdot\text{mol}^{-1}$ ]
40	$H$	Number of nodes in radial direction
41	$i$	Specific enthalpy [ $\text{J}\cdot\text{kg}^{-1}$ ]
42	$j$	Molar flux [ $\text{mol}\cdot\text{m}^{-2}\text{s}^{-1}$ ]
43	$k$	Thermal conductivity [ $\text{W}\cdot\text{m}^{-1}\text{K}^{-1}$ ]
44	$L$	Mechanical power [W]
45	$m$	Mass Flow-rate [ $\text{kg}\cdot\text{s}^{-1}$ ]
46	$M$	Molar weight [ $\text{kg}\cdot\text{mol}^{-1}$ ]

47	$N$	Number of nodes in tangential direction
48	$P$	Pressure [kPa]
49	$Q$	Thermal power [W]
50	$q$	Heat flux per tube unit length [ $\text{kW}\cdot\text{m}^{-1}$ ]
51	$r$	Outer tube radius [m]
52	$R$	Grid ratio in normal direction
53	$Re$	Reynolds Number
54	$S$	Volumetric entropy generation rate [ $\text{W}\cdot\text{m}^{-3}\text{K}^{-1}$ ]
55	$s$	Molar entropy [ $\text{J}\cdot\text{mol}^{-1}\text{K}^{-1}$ ]
56	$T$	Temperature [K]
57	$u$	Stream-wise velocity [ $\text{m}\cdot\text{s}^{-1}$ ]
58	$v$	Radial velocity [ $\text{m}\cdot\text{s}^{-1}$ ]
59	$V$	Total velocity [ $\text{m}\cdot\text{s}^{-1}$ ]
60	$x$	Local tangential position [m]
61	$y$	Local normal position [m]
62	$Z$	Tube length [m]
63	Greek symbols	
64	$\Gamma$	Mass flow rate per unit length [ $\text{kg}\cdot\text{s}^{-1}\text{m}^{-1}$ ]
65	$\Lambda$	Absorbed vapor per unit length of the tube [ $\text{kg}\cdot\text{s}^{-1}\text{m}^{-1}$ ]
66	$\beta$	Stream-wise Angle [rad]
67	$\delta$	Film Thickness [m]
68	$\varepsilon$	Dimensionless tangential position
69	$\phi$	General parameter identification
70	$\gamma$	Chemical potential [ $\text{J}\cdot\text{mol}^{-1}$ ]

71	$\eta$	Dimensionless normal position
72	$\eta_{\text{Ca}}$	Carnot efficiency
73	$\mu$	Viscosity [Pa·s]
74	$\theta$	Dimensionless temperature
75	$\rho$	Density [kg·m <sup>-3</sup> ]
76	$\sigma$	Irreversibility rate [W·K <sup>-1</sup> ]
77	$\tau$	Shear stress tensor [Pa]
78	$\omega$	LiBr mass concentration
79	Subscripts	
80	0	Standard condition
81	A	Absorber
82	abs	Absorption
83	C	Condenser
84	c	Convection
85	CH	Chiller
86	d	Diffusion
87	E	Evaporator
88	e	Equilibrium
89	f	Friction
90	g	Global
91	G	Generator
92	H2O	Water
93	HT	Heat transformer
94	HP	Heat pump

95	i,j	Node indexes
96	if	Interface
97	in	Inlet
98	min	Minimum
99	RM	Refrigerating machine
100	TM	Thermal machine
101	out	Outlet
102	s	Sub-cooling
103	S	Solution
104	sat	Phases equilibrium
105	t	Thermal
106	v	Vapor
107	w	Wall

108       **1. Introduction**

109   Nowadays the awareness of the environmental issues of the planet steers towards clean and efficient  
110   energy conversion systems. Absorption chillers, heat pumps and heat transformers represent an  
111   opportunity in this direction. The use of the vapor absorption cycle for heat driven energy systems  
112   was among the first popular and widely used methods of refrigeration. Even though the development  
113   of vapor compression cycles has limited the implementation field of vapor absorption systems, the  
114   main benefits of absorption cycle are still evident: since a negligible amount of electricity is needed,  
115   waste heat can be used as the main energy source and higher reliability can be ascribed to the  
116   absence of moving parts. In addition, typically used refrigerant (water or ammonia) are not  
117   responsible of ozone depletion effect.

118 All the real processes occurring in an energy conversion system are associated to an unavoidable  
119 degradation of the original amount of energy. The second law of thermodynamics provides a  
120 qualitative description, which is not confined to engineering, and is critical to identify the limitations  
121 imposed to a physical process. Namely, according to this general design issue, thermal design and  
122 basic thermodynamics are to be employed together with the purpose of identifying the optimum size  
123 or operating regime of a certain engineering system, where by “optimum” the least exergy destroying  
124 condition, which can still assure the fundamental engineering function, is intended. Among the  
125 possible scenarios, the method of entropy generation minimization can be used to evaluate the  
126 irreversibility introduced, characterize the quality of energy-conversion, and develop consistent  
127 criteria for the optimization and control of the system. From this point of view, the enhancement of  
128 efficiency describing the achieved technological development constitutes a secondary result of  
129 entropy generation minimization [1] and entropy can be used to develop useful criteria for system  
130 optimization and control.

131 From the prospective of the global system, authors in [2] and [3] have presented a literature review  
132 of finite-time thermodynamics optimization of absorption refrigeration systems and analyzed the  
133 various possible objective functions. In general, in order to consider the temperature level of the  
134 various heat fluxes involved in the energy conversion process, a second law approach is particularly  
135 significant for the characterization of the performance of heat-driven systems. Exergy-based analyses  
136 of water-lithium bromide absorption refrigeration systems, in both their single [4] and multiple effect  
137 configurations [5], and absorption heat transformers [6], have been performed to evaluate  
138 performance and exergy loss of the system and its components.

139 The fundamental heat and mass-transfer processes constituting the absorption cycle are realized  
140 inside specific heat exchangers, whose characteristics have decisive effects on the overall system  
141 efficiency, on its dimensions and on its cost. In the conventional case of falling film heat exchangers,

142 high transfer coefficient and low pressure drop can be obtained. However, the attempt to  
143 experimentally and theoretically describe the complex heat and mass-transfer mechanism occurring  
144 inside these devices is still incomplete and has not led to conclusive approaches. As a rule, [4],  
145 [5], [6] and [7] have highlighted that the maximum exergy destruction occurs in the absorber and the  
146 analysis and optimization of this device is crucial for the absorption system in refrigerator and heat  
147 transformer applications.

148 In terms of modelling efforts, [8], [9], [10], [11] and [12] have discussed simplified models for falling  
149 film absorption of water vapor over a horizontal tube. Similarly, they solved the problem with a finite  
150 difference method and studied the effect of different parameters on the coupled heat and mass  
151 transfer processes.

152 To the authors' knowledge, few studies [1], [13], [14], [15] performing a second law analysis of  
153 absorption devices have been previously carried out. In particular, [16] and [17] report a second law-  
154 based analytical study for gas absorption into a laminar, gravity-driven, viscous, incompressible,  
155 isothermal liquid film. The main conclusion states that entropy generation is mainly ruled by the  
156 coupling effects between heat and mass transfer in proximity of the gas-liquid interface and by  
157 viscous irreversibility near the solid wall. However, heat transfer and the tube wall geometry have  
158 not been included in the problem. Simultaneous cooling and absorption allow the process to be  
159 maintained far from the thermodynamic equilibrium at which absorption won't occur any longer.

160 The main purposes of this work stem from the proper expression of the local entropy generation rate  
161 representing real LiBr-H<sub>2</sub>O absorptive films. A local analysis can be carried out by means of the  
162 numerical solution of energy and species transport equations around a cooled horizontal tube. Since  
163 entropy generation minimization has been widely accepted as a method for heat exchangers' design  
164 and optimization, a parametric study based on entropy generation analysis is performed. Finally, a  
165 simple thermodynamic analysis shows that the absorption system performance can be improved by

166 means of the optimization of the absorber design and operational regime when suitable  
167 dimensionless groups, accounting for the total entropy generation introduced, are defined as  
168 objective parameters.

## 169       **2. Model description and numerical solution**

170 A single horizontal tube is considered and the LiBr-H<sub>2</sub>O solution flows viscously down over it driven  
171 by gravity as a laminar incompressible liquid, while vapor mass transfer process occurs at the film  
172 interface. The heat released by the absorption is rejected to the cooling water flowing inside the tube.  
173 The system under analysis is schematically showed in Figure 1. Heat and mass transfer characteristics  
174 of the absorber tube have been obtained by numerically solving transport of mass and energy  
175 equations, under the following main assumptions:

- 176       - Steady and laminar flow without interfacial waves.
- 177       - Thermodynamic equilibrium with the vapor at the film interface.
- 178       - Negligible shear force between the liquid film and the vapor.
- 179       - Disturbance at the edges of the system are neglected assuming that both the tube  
180       circumference and length are large if compared to the film thickness.
- 181       - Physical properties are calculated with reference to the inlet values of concentration and  
182       temperature, but remain constant while the film is flowing on the tube.
- 183       - Negligible heat transfer to the vapor phase.
- 184       - Constant temperature of tube surface.
- 185       - Body fitted coordinates (x along the tube surface and y normal to it at any point) are used  
186       because the film thickness is small if compared to the tube circumference [12].

**Figure 1 Local coordinate system of the flowing film**

The tangential and normal velocity components (respectively, eqs. 1 and 2), from continuity and momentum equations (based on Nusselt boundary layer assumptions), are used for the numerical solution of the transport of mass and energy (respectively, eqs. 4 and 3).

$$u = \frac{\rho g}{\mu} \sin \beta \left( \delta y - \frac{1}{2} y^2 \right) \quad (1)$$

$$v = -\frac{\rho g y^2}{2\mu} \left[ \frac{d\delta}{dx} \sin \beta + \frac{1}{r} \left( \delta - \frac{y}{3} \right) \cos \beta \right] \quad (2)$$

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = a \frac{\partial^2 T}{\partial y^2} \quad (3)$$

$$u \frac{\partial \omega}{\partial x} + v \frac{\partial \omega}{\partial y} = D \frac{\partial^2 \omega}{\partial y^2} \quad (4)$$

Where the film thickness is given by eq. 5 [12].

$$\delta = \left( \frac{3\mu\Gamma}{\rho^2 g \sin \beta} \right)^{1/3} \quad (5)$$

198 The problem formulation needs to be closed by consistent initial and boundary conditions. The initial  
 199 conditions correspond to the solution temperature and concentration at the distributor, otherwise  
 200 assuming that a complete mixing occurs, to the bulk values of the previous tube.

201 At  $x=0$  and  $0 < y < \delta$ ;  $T=T_{in}$ ,  $\omega=\omega_{in}$

202 The boundary conditions on the tube surface set a constant value of temperature and null diffusion.

203 At  $y=0$ ;  $T=T_w$ ,  $\frac{\partial \omega}{\partial y} = 0$

204 At the interface, temperature is related to interface concentration and the heat exchanger pressure  
 205 by the equilibrium condition.

206 At  $y=\delta$ ;  $T=T_{sat}(\omega_{if}, P)$ ,  $\omega=\omega_{if}$

207 The interface concentration is determined from Fick's law of diffusion:

$$208 \quad G_v = -\frac{\rho D}{\omega_{if}} \frac{\partial \omega}{\partial y} \quad (6)$$

209 And the heat produced by absorption is conducted through the film towards the tube surface:

$$210 \quad G_v i_{abs} = k \frac{\partial T}{\partial y} \quad (7)$$

211 The solution approach adopted introduces a dimensionless coordinate transformation in order to  
 212 map the flow domain in the physical space to a simple rectangular domain in the computational and  
 213 is parallel to [18]. The dimensionless variables considered in the circumferential and radial directions  
 214 are:

$$215 \quad \varepsilon = \frac{x}{\pi r} = \frac{\beta}{\pi} \quad (8)$$

$$216 \quad \eta = \frac{y}{\delta} \quad (9)$$

217 A cosine type grid is employed in the  $\eta$  direction to make the grid finer where steeper gradients are  
 218 expected, i.e. near the tube wall ( $\eta=0$ ) surface and at the interface ( $\eta=1$ ). First order backward

219 difference is applied for the convective term in the  $\varepsilon$  direction for both energy and species transport  
220 equations. In the  $\eta$  direction, second order central difference scheme is used both for the first and  
221 the second derivative [19], respectively belonging to the convective and diffusive terms.  
222 A second order backward difference scheme is used for the first derivative of diffusion terms of the  
223 boundary conditions at the interface. While, a second order forward difference is used for the first  
224 derivative of concentration boundary condition at the wall.  
225 The calculation is performed between  $\beta=\pi/N$  and  $\beta=\pi(N-1)/N$  because of the definition domain of  
226 the velocity field (eq. 1 and 2).

### 227 **3. Mathematical formulation of Entropy generation**

228 From the calculated temperature, velocity and concentration fields, a local irreversibility analysis of  
229 water vapor absorption through a laminar, gravity driven, viscous, incompressible liquid film, flowing  
230 over a cooled horizontal tube, is performed and different entropy sources are distinguished. Owing  
231 to the simultaneous heat and mass transfer, four sources of irreversibility can be recognized and,  
232 respectively, related to heat transfer, fluid friction, coupled effects between heat and mass transfer  
233 by convection and coupled effects between heat and mass transfer by diffusion.

234 Further assumptions are required for the entropy generation mathematical formulation:

- 235 - Physical absorption (no chemical reactions)
- 236 - Steady state regime of the two dimensional flow
- 237 - Newtonian and incompressible, liquid film (LiBr-H<sub>2</sub>O solution)
- 238 - Water vapor absorbed is considered as a perfect gas
- 239 - The absorption process takes place at constant pressure

240 The existence of thermal, velocity and concentration gradients in the computational field  
241 representing the absorptive film yields a non-equilibrium state, which is responsible of entropy

variations (generally referred to as entropy generation). According to the problem formulation and to the introduced assumptions, the volumetric rate of entropy generation due to friction, heat and mass transfer is given by,

$$S_g = \frac{\mathbf{r}}{q} \cdot \frac{\mathbf{u}}{\nabla} \left( \frac{1}{T} \right) + \frac{\overline{\overline{\tau}} : \overline{\overline{\nabla}}(V)}{T} - \frac{1}{T} \frac{\mathbf{u}}{j_v} \cdot \frac{\mathbf{u}}{\nabla}(\gamma_v) \quad (10)$$

The three terms in eq. 10 can be related, respectively, to heat transfer, fluid friction and mass transfer irreversibilities. The heat flux  $q$  includes the heat flux given by the Fourier Law and the enthalpy flux due to species diffusion.

$$\frac{\mathbf{r}}{q} = -k_s \frac{\mathbf{u}}{\nabla}(T) - h_v \frac{\mathbf{u}}{j_v} \quad (11)$$

As a result, a rearrangement of the expression gives eq.12.

$$S_g = \frac{1}{T^2} k_s \frac{\mathbf{u}}{\nabla}(T)^2 + \frac{1}{T^2} h_v \frac{\mathbf{u}}{j_v} \cdot \frac{\mathbf{u}}{\nabla}(T) + \frac{\overline{\overline{\tau}} : \overline{\overline{\nabla}}(V)}{T} - \frac{1}{T} \frac{\mathbf{u}}{j_v} \cdot \frac{\mathbf{u}}{\nabla}(\gamma_v) \quad (12)$$

Considering the absorbed water vapor as an ideal gas and the only species diffusing through the liquid solution, its molar concentration  $C_v$  can be derived directly from the mass concentration field of LiBr ( $\omega$ ) resulting from the solution of energy and species transport equations.

$$C_{v,ij} = \frac{\rho_s}{M_{H_2O}} (1 - \omega_{ij}) - \frac{\rho_s}{M_{H_2O}} (1 - \omega_{in}) \quad (13)$$

The molar chemical potential of the vapor can be calculated by eq. 14, as [20].

$$\gamma_v(T, P_0) = c_{p,v}(T - T_0) - T c_{p,v} \ln \left( \frac{T}{T_0} \right) + h_{v,0}(T_0, P_0) - T s_{v,0}(T_0, P_0) \quad (14)$$

Where  $P_0$  and  $T_0$  are the standard values of pressure and temperature, respectively, 1 atm and 298 K. Standard enthalpy and entropy refer to the corresponding thermodynamic state.

The expression of vapor molar enthalpy and entropy are, respectively, given by,

$$h_v = c_{p,v}(T - T_0) + h_{v,0} \quad (15)$$

$$s_v = c_{p,v} \ln \left( \frac{T}{T_0} \right) + s_{v,0} \quad (16)$$

The shear stress is given by eq. 17.

$$\tau = \mu_s \left( \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right) \quad (17)$$

Thus, the local volumetric entropy generation rate can be expressed as,

$$S_g = \frac{k_s}{T^2} \left[ \left( \frac{\partial T}{\partial x} \right)^2 + \left( \frac{\partial T}{\partial y} \right)^2 \right] + \frac{\mu_s}{T} \left\{ 2 \left[ \left( \frac{\partial u}{\partial x} \right)^2 + \left( \frac{\partial v}{\partial y} \right)^2 \right] + \left[ \left( \frac{\partial u}{\partial y} \right) + \left( \frac{\partial v}{\partial x} \right) \right]^2 \right\} + \frac{h_v}{T^2} \left[ j_{v,x} \left( \frac{\partial T}{\partial x} \right) + j_{v,y} \left( \frac{\partial T}{\partial y} \right) \right] - \frac{1}{T} \left[ j_{v,x} \left( \frac{\partial \gamma_v}{\partial x} \right) + j_{v,y} \left( \frac{\partial \gamma_v}{\partial y} \right) \right] \quad (18)$$

The transverse and axial molar fluxes are, respectively, given by,

$$j_{v,x} = C_v u - D_{vS} \frac{\partial C_v}{\partial x} \quad (19)$$

$$j_{v,y} = C_v v - D_{vS} \frac{\partial C_v}{\partial y} \quad (20)$$

By substituting the fluxes and enthalpy expressions and by calculating the derivatives of the molar chemical potential, the expression can be finally reorganized for representing the case of gas absorption into a falling liquid film.

$$S_g = \frac{k_s}{T^2} \left[ \left( \frac{\partial T}{\partial x} \right)^2 + \left( \frac{\partial T}{\partial y} \right)^2 \right] + \frac{\mu_s}{T} \left\{ 2 \left[ \left( \frac{\partial u}{\partial x} \right)^2 + \left( \frac{\partial v}{\partial y} \right)^2 \right] + \left[ \left( \frac{\partial u}{\partial y} \right) + \left( \frac{\partial v}{\partial x} \right) \right]^2 \right\} + \left[ c_{p,v} (T - T_0) + h_{v,0} + T \left( c_{p,v} \ln \left( \frac{T}{T_0} \right) + s_{v,0} \right) \right] \left[ \frac{C_v}{T^2} \left( v \frac{\partial T}{\partial y} + u \frac{\partial T}{\partial x} \right) - \frac{D_{vS}}{T^2} \left( \frac{\partial C_v}{\partial y} \frac{\partial T}{\partial y} + \frac{\partial C_v}{\partial x} \frac{\partial T}{\partial x} \right) \right] \quad (21)$$

Different terms, related to different entropy variation sources, can be distinguished. The first term of the right-hand side of eq. 21 stands for the irreversibility due to heat transfer  $S_t$ .

$$S_t = \frac{k_s}{T^2} \left[ \left( \frac{\partial T}{\partial x} \right)^2 + \left( \frac{\partial T}{\partial y} \right)^2 \right] \quad (22)$$

The second term is due to fluid friction.

$$S_f = \frac{\mu_s}{T} \left\{ 2 \left[ \left( \frac{\partial u}{\partial x} \right)^2 + \left( \frac{\partial v}{\partial y} \right)^2 \right] + \left[ \left( \frac{\partial u}{\partial y} \right) + \left( \frac{\partial v}{\partial x} \right) \right]^2 \right\} \quad (23)$$

The third and the fourth terms are related to the coupling effects between heat and mass transfer, by convection and diffusion, respectively.

$$S_c = \left[ c_{p,v}(T - T_0) + h_{v,0} + T \left( c_{p,v} \ln \left( \frac{T}{T_0} \right) + s_{v,0} \right) \right] \left[ \frac{C_v}{T^2} \left( v \frac{\partial T}{\partial y} + u \frac{\partial T}{\partial x} \right) \right] \quad (24)$$

$$S_d = - \left[ c_{p,v}(T - T_0) + h_{v,0} + T \left( c_{p,v} \ln \left( \frac{T}{T_0} \right) + s_{v,0} \right) \right] \left[ \frac{D_{vS}}{T^2} \left( \frac{\partial C_v}{\partial y} \frac{\partial T}{\partial y} + \frac{\partial C_v}{\partial x} \frac{\partial T}{\partial x} \right) \right] \quad (25)$$

The solution properties are calculated for the inlet values of temperature, pressure and concentration, with reference to [21].

#### 4. Results

A general analysis has been carried out for typical conditions of a single absorber tube in a chiller and in a heat transformer, respectively working with coolant temperatures of 32 °C and 83 °C, and outside pressure of 1.0 kPa and 12.5 kPa. The initial conditions of the LiBr-H<sub>2</sub>O solution film have been set at the equilibrium temperature for a 60% concentration solution at the absorber vapour pressure. Furthermore, the variation of mass flow rate due to absorption of water vapor is considered negligible. This assumption is valid for a mass flow-rate higher than 0.001 kg·m<sup>-1</sup>s<sup>-1</sup>, and accordingly, this analysis has been performed in a consistent mass flow-rate range [20]. Since Nusselt integral solution for velocity distribution is not defined at the inlet and outlet positions, respectively  $\varepsilon=0$  and

294  $\varepsilon=1$ , the total entropy generation  $S_G$  has been evaluated between  $\varepsilon=1/N$  and  $\varepsilon=N-1/N$  inside the  
 295 whole film thickness.

 298 **Figure 2 Local entropy generation rate [ $\text{kW}\cdot\text{m}^{-3}\text{K}^{-1}$ ];  $m=0.045\text{ kg}\cdot\text{m}^{-1}\text{s}^{-1}$ ,  $\omega_n=60\%$ , (a)  $T_{in}=46.6\text{ }^{\circ}\text{C}$ ,  
 299  $P=1\text{ kPa}$ ,  $T_w=32\text{ }^{\circ}\text{C}$ , (b)  $T_{in}=97.1\text{ }^{\circ}\text{C}$ ,  $P=12.5\text{ kPa}$ ,  $T_w=83\text{ }^{\circ}\text{C}$ , flowing over a tube with outer radius  
 300  $r=8\text{ mm}$ .**

301 The total entropy generation rate per unit volume  $S_g$  for an absorptive LiBr-H<sub>2</sub>O solution flowing on  
 302 a cooled horizontal tube is illustrated in Figure 2 as the superimposition of the different groups  
 303 previously identified.  $S_g$  shows a local minimum in the radial direction except in the first and the last  
 304 parts of the tube surface, where the total entropy generation rate is relentlessly decreasing from the  
 305 wall to the film interface. The minimum is determined by the contemporaneity of wall heat transfer,  
 306 friction and coupled heat and mass transfer at the interface, and it is positioned at the penetration  
 307 distance of the diffusing vapor inside the film. In the second half of the tube surface the total entropy  
 308 generation rate  $S_g$  at the film interface assumes negative values, due to the only negative  
 309 contribution of the group related to the coupled effects of mass convection and heat transfer  $S_c$ : this  
 310 behaviour can be explained considering that the local temperature decreases in the stream-wise

311 direction and vapor concentration  $C_v$  increases in that region (eq. 24, where the term  $C_v u / T^2 \cdot \partial T / \partial x$  is  
312 dominant).

313 In order to compare the performance of the system with the actual amount of irreversibility  
314 introduced, the local volumetric entropy generation rate is integrated over the film physical domain.  
315 Considering film thickness and the circumference of the tube the entropy generation per unit length  
316 of the tube  $E$  is defined by eq. 26.

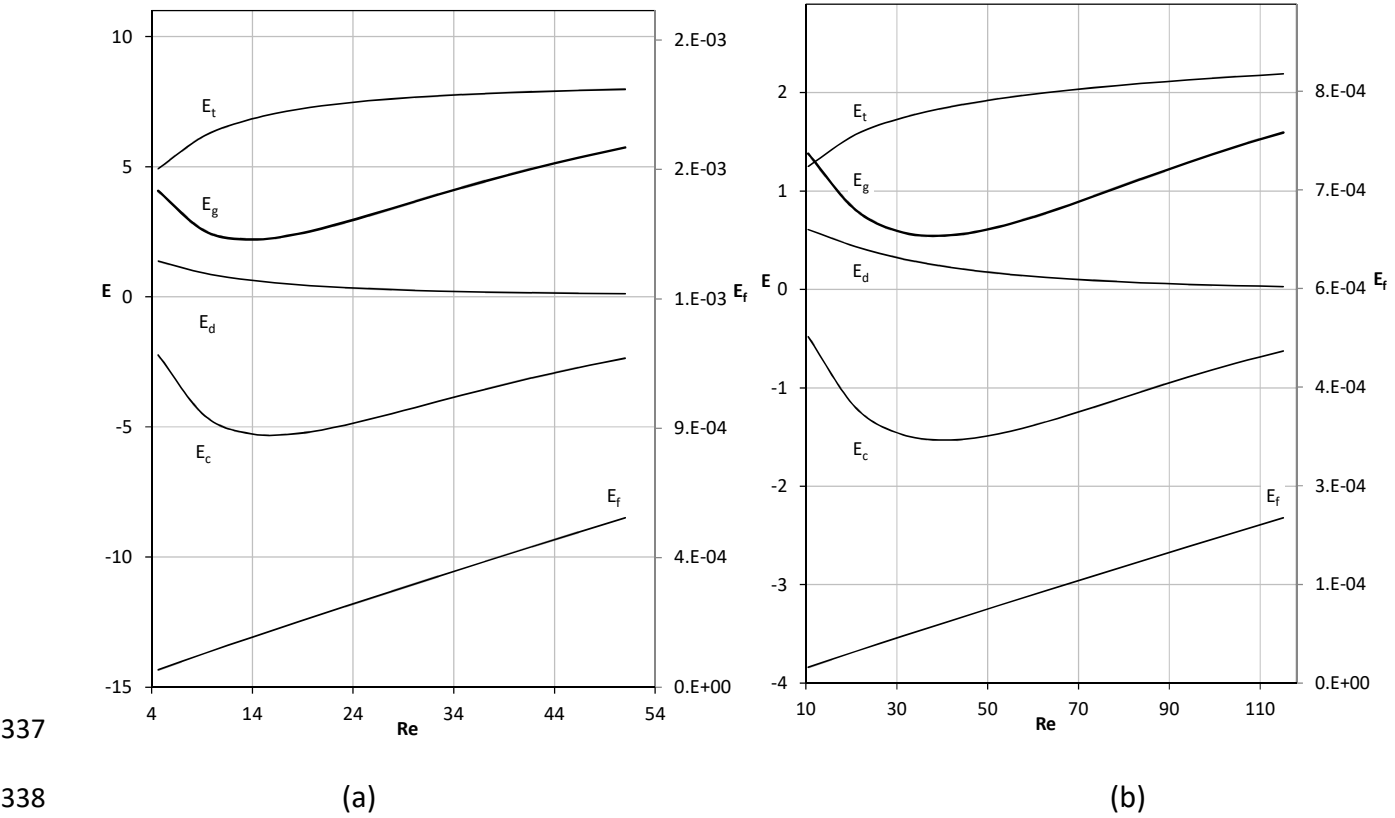

$$317 \quad E = 2 \int_0^{\pi r} \int_0^{\delta} S dy dx \quad (26)$$

318 The parametric analysis performed ascertains that a minimum entropy generation can always be  
319 identified in terms of the film Reynolds number (defined by eq. 27), which establishes the optimal  
320 thermodynamic condition in terms of entropy generation rate per unit length (Figure 3). As previously  
321 stated, in this work by “optimum” the least irreversible operating condition for a specified objective  
322 is meant, or otherwise, the most desirable trade-off between two or more competing irreversibilities  
323 [1]. Entropy generation minimization had been also applied to design counter-flow heat exchangers  
324 [22], [23], [24] or desiccant systems [25], [26], [27], [28].

$$325 \quad Re = \frac{4\Gamma}{\mu} \quad (27)$$

326 In general, higher temperature applications have lower entropy generation and cope with higher  
327 solution Reynolds. The general trend of the different groups can be examined in Figure 3. Increasing  
328 Reynolds numbers determine increasing friction and decreasing absorption rates, and their  
329 respective entropy generation groups ( $E_f$  and  $E_d$ ) show consistent trends. The combined effects of  
330 increasing extension of the entrance region, increasing film thickness and decreasing absorption heat  
331 release, globally establish an increasing behaviour of the thermal related irreversibilities  $E_t$ . The  
332 entropy generation group related to the coupled effects of mass convection and heat transfer  $E_c$

333 shows a local minimum (maximum of the absolute value), which can be explained considering that  
 334 when Reynolds number is increased convection is amplified while absorption heat release is reduced.  
 335 As already pointed out regarding the corresponding term of volumetric entropy generation, this  
 336 group assumes negative values.

339 **Figure 3 Various entropy generation groups per unit length of the tube [ $W \cdot m^{-1} K^{-1}$ ] as a function of**  
 340 **film Reynolds number; (a)  $T_w=32^\circ C$ ,  $\omega_{in}=60\%$ ,  $T_{in}=46.6^\circ C$ ,  $P=1kPa$ , (b)  $T_w=83^\circ C$ ,  $\omega_{in}=60\%$ ,  $T_{in}=97.1^\circ C$ ,**  
 341  **$P=12.5kPa$**

342 Absorber design and operability parameters can be considered in the analysis. A graphical parametric  
 343 study is performed evaluating the influence on the entropy generation rate of a different tube radius,  
 344 coolant inlet temperature and inlet solution temperature as function of the film Reynolds number.  
 345 At first, equilibrium of the inlet solution with respect to the vapour temperature (and pressure) is  
 346 considered.

347 The influence of the radius on the global entropy generation and on each entropy generation group  
 348 as a function of solution mass flow rate (e.g. Reynolds Number, defined by eq. 27), for fixed inlet and  
 349 boundary conditions is presented, respectively, in Figure 4 and Figure 5. As a rule, lower tube radii  
 350 present lower entropy generation rates per unit length and match with lower solution Reynolds  
 351 values (Figure 4). The trend of the global entropy generation shows a minimum value and the  
 352 corresponding Reynolds number could be considered as a least irreversibility operative condition.  
 353 For the chiller application case (Figure 4a), least irreversibility Reynolds numbers of 10, 14 and 23 are  
 354 obtained, respectively, for tube radii of 5, 8 and 11mm. For the same values of tube radii, but for an  
 355 absorber operating at reference conditions for a heat transformer, the least irreversibility Reynolds  
 356 numbers are, respectively, 31, 42 and 52 (Figure 4b). These values have been obtained without  
 357 considering partial wetting of the exchange surface, but usually they correspond to solution mass  
 358 flow rates which are not able to assure complete wetting, unless tension-active surfactants are added  
 359 to the solution.

360  
 361 (a) (b)  
 362 **Figure 4 Entropy generation rate per unit length [ $\text{W}\cdot\text{m}^{-1}\text{K}^{-1}$ ] as a function of Reynolds number for**  
 363 **different values of the tube radius; (a)  $T_w=32^\circ\text{C}$ ,  $\omega_{in}=60\%$ ,  $T_{in}=46.6^\circ\text{C}$ ,  $P=1\text{kPa}$ , (b)  $T_w=83^\circ\text{C}$ ,**  
 364  **$\omega_{in}=60\%$ ,  $T_{in}=97.1^\circ\text{C}$ ,  $P=12.5\text{kPa}$**

365 Figures 5(a-b) show the effect of different tube radii on each entropy generation group. A bigger  
 366 radius increases the absolute value of every entropy generation group. In fact, when entropy  
 367 generation is integrated over the film thickness and the tube circumference the group related to  
 368 thermal irreversibility  $E_t$  shows a relaxingly-increasing trend with respect to Reynolds number.  
 369 Contrarily, the vapor diffusion related irreversibility  $E_d$  is characterised by a relentlessly decreasing  
 370 trend. The group related to the coupled effects of mass convection and heat transfer  $E_c$  has a critical  
 371 influence on the global trend of the entropy generation rate per unit length  $E_g$  and, as already pointed  
 372 out, it shows a local minimum, which can be explained considering that, increasing Reynolds number,  
 373 the velocity field is intensified while absorption heat release is reduced. A greater outer radius moves  
 374 the minimum to higher  $Re$  and to lower values of  $E_c$ . Finally, the greater the tube radius the higher  
 375 the friction related irreversibility  $E_f$ .  
 376 Comparing chiller and heat transformer applications, as a rule, the first corresponds to higher entropy  
 377 generation rate and the latter highlights a greater impact of the diffusion related irreversibility.

(a)

(b)

380 **Figure 5 Effect of different radii on the various entropy generation groups [ $\text{W}\cdot\text{m}^{-1}\text{K}^{-1}$ ]; (a)  $T_w=32^\circ\text{C}$ ,**  
 381  **$\omega_{in}=60\%$ ,  $T_{in}=46.6^\circ\text{C}$ ,  $P=1\text{kPa}$ , (b)  $T_w=83^\circ\text{C}$ ,  $\omega_{in}=60\%$ ,  $T_{in}=97.1^\circ\text{C}$ ,  $P=12.5\text{kPa}$**

382 In general, a lower tube wall temperature increases heat transfer and, increasing the driving force  
 383 for vapor absorption, mass transfer at the interface. Accordingly, Figure 6 makes evidence of a higher  
 384 entropy generation when tube wall temperature is decreased, while the optimal Reynolds is weakly  
 385 dependent on this parameter.

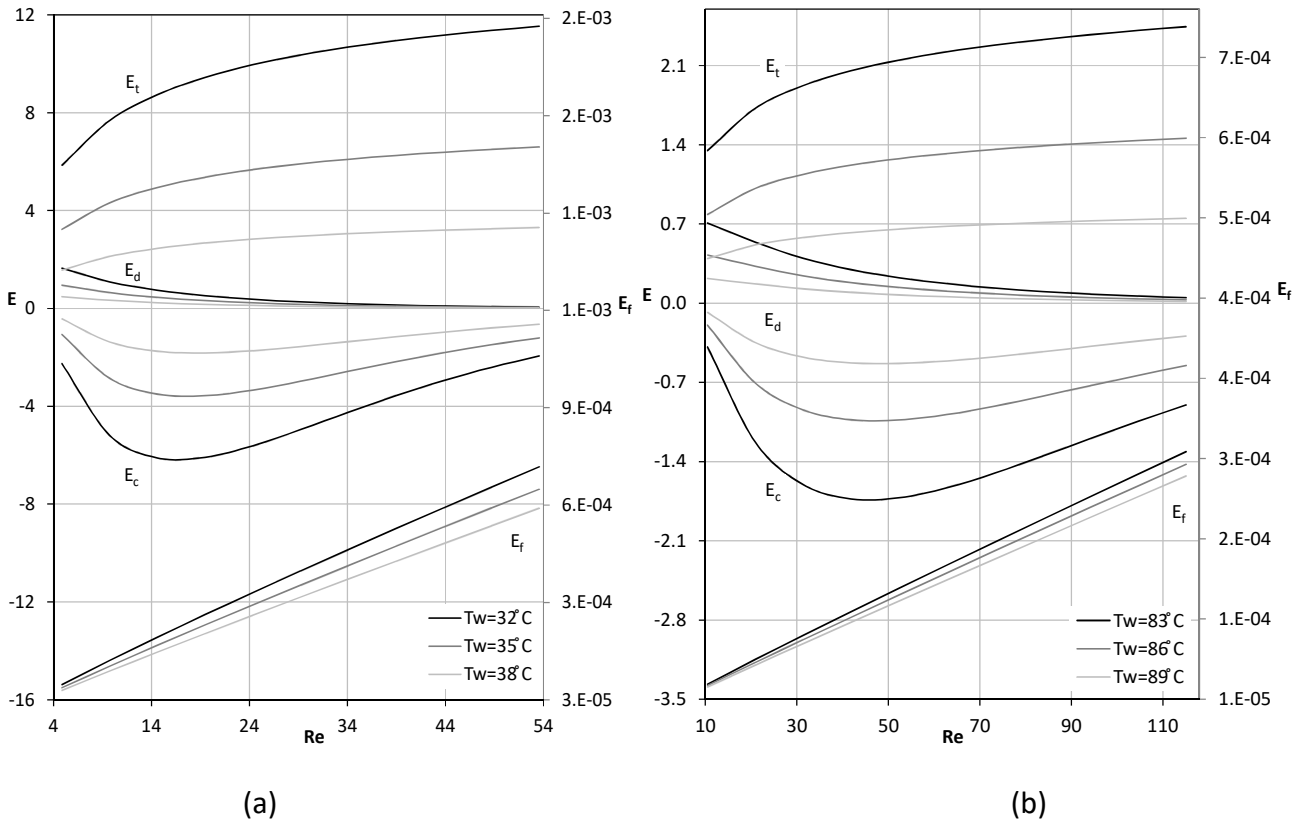

386 (a) (b)

387

388 **Figure 6 Entropy generation rate per unit length [ $\text{W}\cdot\text{m}^{-1}\text{K}^{-1}$ ] as a function of Reynolds number for**  
 389 **different values of the tube wall temperature; (a)  $r=9\text{mm}$ ,  $\omega_{in}=60\%$ ,  $T_{in}=46.6^\circ\text{C}$ ,  $P=1\text{kPa}$ , (b)**  
 390  **$r=9\text{mm}$ ,  $\omega_{in}=60\%$ ,  $T_{in}=97.1^\circ\text{C}$ ,  $P=12.5\text{kPa}$**

391 Figures 7(a-b) describe the effect of different tube wall temperatures on the various entropy  
 392 generation group. A lower wall temperature increases temperature gradients and, once the  
 393 temperature gradient reaches the interface, also concentration gradients. Also friction related  
 394 irreversibility  $E_f$  (eq. 23) is affected indirectly by a different wall temperature which determines a  
 395 different temperature field.

**Figure 7 Effect of different wall temperatures on the various entropy generation groups [ $\text{W}\cdot\text{m}^{-1}\text{K}^{-1}$ ]; (a)  $r=9\text{mm}$ ,  $\omega_{in}=60\%$ ,  $T_{in}=46.6\text{ }^\circ\text{C}$ ,  $P=1\text{kPa}$ , (b)  $r=9\text{mm}$ ,  $\omega_{in}=60\%$ ,  $T_{in}=97.1\text{ }^\circ\text{C}$ ,  $P=12.5\text{kPa}$**

Furthermore, in order to analyse the effect of a different equilibrium temperature at the interface (and, due to the equilibrium hypothesis, a different absorber pressure), the calculations are extended over a range of different inlet solution temperatures for both the chiller and the heat transformer applications. Since the tube wall temperature is maintained constant, different inlet temperatures have a similar effect to that of different wall temperatures for a fixed inlet condition. However, for the same temperature difference  $T_i - T_w$ , a change in the inlet temperature value brings about a smaller entropy generation than that correspondingly obtained by changing the wall temperature. Also, lower the inlet temperatures are associated to slightly lower Reynolds corresponding to the optimal condition (Figure 8).

**Figure 8 Entropy generation per unit length [ $\text{W}\cdot\text{m}^{-1}\text{K}^{-1}$ ] as a function of Reynolds number for different inlet temperatures; (a)  $r=9\text{mm}$ ,  $\omega_{\text{in}}=60\%$ ,  $T_w=32^\circ\text{C}$ , (b)  $r=9\text{mm}$ ,  $\omega_{\text{in}}=60\%$ ,  $T_w=83^\circ\text{C}$**

Acting again on the temperature difference  $T_i-T_w$ , inlet solution temperature variations have similar effects to those of a different wall temperature on the entropy generation groups as function of film Reynolds number and the corresponding graph is omitted.

## 5. Heat and mass transfer optimization

As a rule, the formulation of thermodynamic optimization criteria has always accompanied the analysis of energy systems in order to improve their performance. Since the development of finite-time thermodynamics, the attention has been moved towards the concept of non-equilibrium processes and their related irreversibility sources. The use of absorption systems has attracted a remarkable attention and shown a great potential in the utilization of low-grade heat sources [29] [30] [31] [32]. Both chiller and heat transformer configurations have been generally analysed from a first and second principle point of view [33] [34] [35] [36] [37] [38]. Based on the previous thermodynamic analysis of the irreversibility associated to the absorption of vapour and the heat transfer in a falling film configuration of the absorber, this paper aims at the definition of proper dimensionless parameters for the optimization of this component regarding the ultimate duty of the

427 system. In general, a heat transformer is a device which aims at delivering heat at a higher  
 428 temperature than the given temperature of the heat source. The component of the plant which  
 429 actuates this final heat transfer is the absorber. Absorption refrigeration machines are supposed to  
 430 extract heat at a lower temperature than those of the ambient and the driving-fluid in the generator.  
 431 The cooling effect is realized by the evaporation of the condensed refrigerant, which is then absorbed  
 432 by the solution inside the absorber, in order to be effectively pumped at the generator pressure level  
 433 and start the cycle again. Accordingly, the best thermodynamic condition of the absorber operability  
 434 in the two application cases considered corresponds to two different conditions.  
 435 For the first principle of thermodynamics, the COP of an absorption system can be expressed in a  
 436 general way by eq. 28 for a refrigeration application and eq. 29 in case of heat boosting one.

$$437 \quad COP_{CH} = \frac{Q_E}{L} \frac{L}{Q_G} = \frac{Q_E}{Q_C - Q_E} \frac{Q_G - Q_A}{Q_G} = \frac{Q_E}{T_C \left( \frac{Q_C}{T_C} - \frac{Q_E}{T_C} \right)} \frac{T_A \left( \frac{Q_G}{T_A} - \frac{Q_A}{T_A} \right)}{Q_G} \quad (28)$$

$$438 \quad COP_{HT} = \frac{Q_A}{L} \frac{L}{Q_G} = \frac{Q_A}{Q_A - Q_E} \frac{Q_G - Q_C}{Q_G} = \frac{Q_A}{T_E \left( \frac{Q_A}{T_E} - \frac{Q_E}{T_E} \right)} \frac{T_C \left( \frac{Q_G}{T_C} - \frac{Q_C}{T_C} \right)}{Q_G} \quad (29)$$

439 Introducing the second principle of thermodynamics, applied to irreversible cycles where isothermal  
 440 heat transfer without any temperature difference at the heat exchange occurs, is possible to state,

$$441 \quad \frac{Q_C}{T_C} = \frac{Q_E}{T_E} + \sigma_{EC} \quad , \quad \frac{Q_A}{T_A} = \frac{Q_G}{T_G} + \sigma_{GA} \quad (30)$$

$$442 \quad \frac{Q_A}{T_A} = \frac{Q_E}{T_E} + \sigma_{EA} \rightarrow \frac{Q_E}{T_E} = \frac{Q_A}{T_A} - \sigma_{EA} \quad , \quad \frac{Q_C}{T_C} = \frac{Q_G}{T_G} + \sigma_{GC} \quad (31)$$

443 Accordingly, the expression of the system performance in terms of COP can be rearranged  
 444 highlighting the influence of components irreversibility.

$$COP_{CH} = \frac{Q_E}{T_C \left( \frac{Q_E}{T_E} + \sigma_{EC} - \frac{Q_E}{T_C} \right)} \frac{T_A \left( \frac{Q_G}{T_A} - \frac{Q_G}{T_G} - \sigma_{GA} \right)}{Q_G} = \frac{1 - \frac{T_A}{T_G} - \frac{\sigma_{GA} T_A}{Q_G}}{\frac{T_C}{T_E} - 1 + \frac{\sigma_{EC} T_C}{Q_E}} = \frac{\eta_{CaTM-GA} - \frac{\sigma_{GA} T_A}{Q_G}}{\frac{1}{\eta_{CaRM-EC}} + \frac{\sigma_{EC} T_C}{Q_E}} \quad (32)$$

$$COP_{HT} = \frac{Q_A}{T_E \left( \frac{Q_A}{T_E} - \frac{Q_A}{T_A} + \sigma_{EA} \right)} \frac{T_C \left( \frac{Q_G}{T_C} - \frac{Q_G}{T_G} - \sigma_{GC} \right)}{Q_G} = \frac{1 - \frac{T_C}{T_G} - \frac{\sigma_{GC} T_C}{Q_G}}{1 - \frac{T_E}{T_A} + \frac{\sigma_{EA} T_E}{Q_A}} = \frac{\eta_{CaTM-GC} - \frac{\sigma_{GC} T_C}{Q_G}}{\frac{1}{\eta_{CaHP-EA}} + \frac{\sigma_{EA} T_E}{Q_A}} \quad (33)$$

Broadly speaking, adopting a comprehensive point of view for chiller and heat transformer application cases, eq. 32 and 33 highlight the effect of irreversibility on the system performance. They make evidence of the importance to minimize component irreversibility, or more precisely, they states that by maximizing the dimensionless groups “ $Q/\sigma T$ ” the efficiency of the system is improved. Even though the expressions obtained for the system performance are based on a simplified approach, they make evidence of a dimensionless group, related to the irreversibilities, that indicate a way to improve the system performance by acting also on a single device (in this case the absorber of the absorption system). In a chiller or heat pump application case, the optimal performance can be identified by the condition at which the absorber operates at the maximum absorption rate with the least thermal power to be rejected. On the other hand, for a heat transformer, the best operative condition corresponds to the maximum thermal power supplied at high temperature for the least power supplied at the generator. Under this approach, based on the previous dimensionless group, two different dimensionless parameters are introduced for the absorber with respect to the operability of the absorption system. Eq. 34 defines the absorber dimensionless parameter used to maximise heat transfer at the wall with regards to the irreversibility introduced, useful in order to maximize the efficiency of the whole system in a heat transformer application.

$$DQ = \frac{q_w}{E_g T_w} \quad (34)$$

464 By maximizing the parameter  $DQ$  the thermal flux per unit length of the tube is maximized for a  
 465 certain entropy generation inside the falling film. From a different point of view, at the maximum  $DQ$ ,  
 466 the product of the total irreversibility per unit length of the tube and the wall temperature is  
 467 minimized for a certain thermal power per unit length  $q_w$  to the cooling water. The product  $E_g T_w$   
 468 embodies the thermal flux associated to the entropy variation of the whole process, in case this  
 469 would be generated by heat transfer at constant temperature  $T_w$  and represents the loss of available  
 470 thermal power because of the process irreversibility.

471 Similarly, eq. 35 defines the absorber dimensionless group used to maximise absorption at the  
 472 interface with regards to the irreversibility introduced, useful in order to maximize efficiency of the  
 473 absorption system in chiller application.

$$474 \quad DA = \frac{\Lambda i_{abs}}{E_g T_e} \quad (35)$$

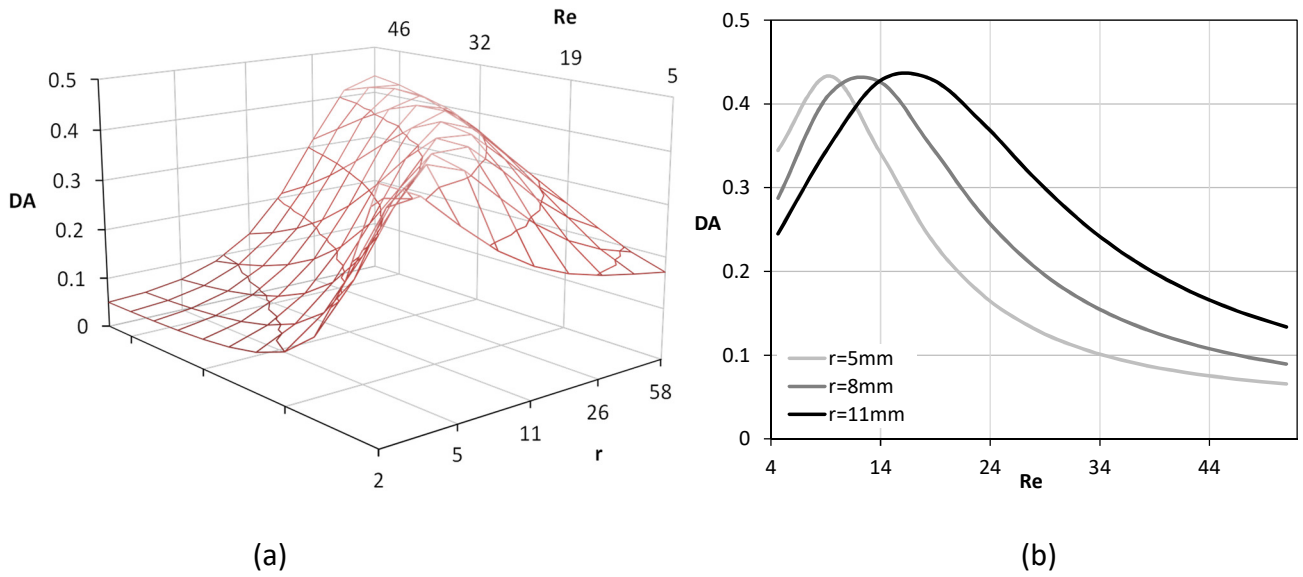

475  $T_e$  is the equilibrium temperature of the solution at concentration  $\omega_n$  (under the assumption of  
 476 thermodynamic equilibrium and constant concentration at the inlet  $T_e = T_{in}$ ) and its physical  
 477 significance corresponds to the temperature that would be reached if thermodynamic equilibrium  
 478 could be obtained without changes in concentration.  $DA$  is the ratio between the entropy generation  
 479 rate that would be produced by the heat transfer of the thermal power per unit length related to the  
 480 release of the heat of absorption by the absorbed vapor at the film interface (at fixed temperature  
 481  $T_e$ ) and the global entropy generation rate per unit length  $E_g$ . Defined in this way,  $DA$  is proportional  
 482 to the  $Q/\sigma T$  group appearing in eq. 32. As a result, by maximizing this parameter the absorbed vapor  
 483 flux per unit length of the tube  $\Lambda$  (and consequently  $Q_E = Z\Lambda(i_{Eout} - i_{Ein})$ ) is maximized for a certain  
 484 entropy generation inside the falling film. Otherwise, at the maximum  $DA$ , the group  $E_g T_e \cdot i_{abs}^{-1}$  is  
 485 minimized for a certain vapor flux per unit length of the tube. This group represents the absorbed  
 486 vapor flux per unit length of the tube associated to the entropy variation of the whole process, in

487 case this would have been generated by the release of the heat of absorption  $i_{abs}$  at constant  
488 temperature  $T_e$ .

489 With respect to the dimensionless parameters introduced, the operability of the absorber can be  
490 investigated and then optimized, respectively, for the absorption chiller and the heat transformer  
491 application cases under analysis.

## 492 **5.1 Chiller**

493 A single value of film Reynolds number which maximizes the dimensionless group  $Q/\sigma T$  ( $DA$  for the  
494 chiller application,  $DQ$  for the heat transformer application) can always be identified. It can be  
495 highlighted that the Reynolds at which this occurs (referred to as optimum Reynolds in the following)  
496 is mainly dependent on the outer tube radius and on the application case (i.e chiller or heat  
497 transformer operability), while a weak influence of the temperature difference between the inlet  
498 solution and the wall temperature is shown (Figures 9 and 10). According to this criterion, optimal  
499 Reynolds number of 9, 13 and 16 correspond, respectively, to tube radii equal to 5mm, 8mm and  
500 11mm for the chiller application case (Figure 9b). In general, the maximum value of  $DA$  is  
501 approximately constant and the film Reynolds that maximise mass transfer, with regard to  $DA$ ,  
502 increases continuously when the tube radius is increased (Figure 9a). Indeed, it can also be stated  
503 that, for any fixed Reynolds there is an optimal value of the tube radius, whose value increases with  
504 Reynolds, but more steeply at low than high values. Accordingly it is possible to identify an asymptotic  
505 maximum value of the radius, above which is not convenient to operate with any mass flow rate.

**Figure 9 Dimensionless parameters  $DA$  as a function of film Reynolds number for different tube radii [mm] at chiller representative conditions;  $\omega_{in}=60\%$ ,  $T_{in}=46.6^\circ\text{C}$ ,  $T_w=32^\circ\text{C}$ ,  $P=1\text{kPa}$  ( $T_e=46.6^\circ\text{C}$ )**

On the other hand, when the difference between inlet and wall temperature is decreased (by increasing the tube wall temperature, i.e. the cooling water temperature, or decreasing the solution inlet temperature), for a fixed Reynolds, the dimensionless group  $DA$  defined show a persistently increasing trend (Figure 10a). This behaviour can be explained considering the fact that a lower temperature of the tube wall increases heat transfer (and indirectly mass transfer), but, at the same time, the irreversibility associated to the absorption process increases at a higher rate. However, an optimal condition in terms of film Reynolds number can always be identified and the corresponding value increases with increasing inlet temperatures of the solution. In particular, optimal Reynolds number of 8, 9 and 11 correspond, respectively, to inlet temperatures equal to  $43^\circ\text{C}$ ,  $45^\circ\text{C}$  and  $47^\circ\text{C}$  for the chiller application case (Figure 10b).

**Figure 10 Dimensionless parameters DA as a function of film Reynolds number for various inlet solution temperatures at chiller representative conditions;  $r=9\text{mm}$ ,  $\omega_{\text{in}}=60\%$ ,  $T_w=32.0^\circ\text{C}$**

The previous calculation has been performed under the assumption of thermodynamic equilibrium between the inlet solution and the vapor at the absorber pressure. However, this condition, which is suitable for a general irreversibility analysis, doesn't usually correspond to the operability of the absorber in actual plants [10]. Accordingly, relaxing this hypothesis, the analysis is extended to conditions which are characterised by the sub-cooling of the inlet solution through the definition of the dimensionless parameter  $\theta$ . The latter (eq. 36) expresses the temperature-boundary and initial conditions in a dimensionless form, linking the sub-cooling of the solution to the temperature difference between the wall and the equilibrium temperature of the inlet solution with the vapour at the absorber pressure.

$$\theta = \frac{T_e - T_{in}}{T_{in} - T_w} \quad (36)$$

In general, by introducing a  $2^\circ\text{C}$  sub-cooling of the solution and keeping it constant, the maximum values of DA move to higher Reynolds (Figure 11). The behaviour of the objective function DA with respect to Reynolds and the tube outer radius in the case of a sub-cooled solution is qualitatively and

quantitatively similar to the case of an inlet solution at thermodynamic equilibrium with the vapor in the absorber (Figure 9).

**Figure 11 Dimensionless parameters DA as a function of film Reynolds number and inlet temperature at chiller representative conditions, 2°C sub-cooling inlet solution,  $r=9\text{mm}$ ,  $\omega_{\text{in}}=60\%$ ,  $T_w=32.0^\circ\text{C}$ ,  $P=1\text{kPa}$**

In order to investigate the influence of the sub-cooling, it is then possible to change the  $\theta$  value keeping fixed  $T_w$  and  $T_e$  value (Figure 12). Higher values of the sub-cooling at the inlet move the maximum to higher Reynolds. Assuming a different standpoint in the optimization of the absorber in a chiller absorption system, we can say that a best value of the solution sub-cooling (i.e.  $\theta$ ) can be identified when both  $T_w$  and  $T_e$  are fixed and furthermore, for a fixed value of  $\theta$ , an optimal Reynolds can always be identified, and, reversely, for a fixed Reynolds an optimal  $\theta$  can be established. What is more, when the absorber works with an inlet solution characterized by the optimal value of the sub-cooling, the corresponding optimal Reynolds is maximized ( $\text{Re}=17$ ). This approach suggests again operating at low solution mass flow rates and with a small temperature difference between the inlet solution and the cooling water. Consistently, in the specific case of falling film heat exchangers, the film thickness constitutes the main heat transfer resistance with the cooling water circulating inside

the tube and it has been theoretically and experimentally recognized that working with reduced solution mass flow rate can improve the system performance. As a result, operability at reduced Reynolds number is attractive for absorption plants, but the tube partial wetting at low solution flow rate needs to be considered as a critical related issue. Regarding the temperature difference between the inlet solution and the cooling water (directly related to the tube wall temperature  $T_w$ ), a low value of this parameter reduces the irreversibility of the process. However, under this point of view in a specific application case the size constraint of the system is expected to be decisive.

**Figure 12 Dimensionless parameters  $DA$  as a function of film Reynolds number and solution sub-cooling at chiller representative conditions,  $r=9\text{mm}$ ,  $\omega_{in}=60\%$ ,  $T_w=32.0^\circ\text{C}$ ,  $T_e=46.6^\circ\text{C}$ ,  $P=1\text{kPa}$**

Both Figures 11 and 12 show a maximum of the  $DA$  value. By considering the physical meaning of this parameter from a system point of view, the chiller (or the heat pump) operates at the maximum absorption rate with the least irreversibility introduced by the absorber, and, bearing in mind eq. 32, this is beneficial to the whole system COP.

## 5.2 Heat transformer

Similarly to the absorption chiller case, the absorber of an absorption heat transformer is studied by means of an analysis of the dimensionless group  $DQ$  defined by Eq. 34. Firstly, thermodynamic

573 equilibrium between the inlet solution and the absorbed vapor is assumed. Figures 13 shows that the  
 574 maximum value of  $DQ$  is roughly constant, but for increasing tube radii, the optimal Reynolds number  
 575 increases as well. According to this criterion, for the heat transformer application case, Reynolds  
 576 number of 30, 40 and 55 maximise heat transfer in the absorber (or minimize the process  
 577 irreversibility), respectively, when the tube radii are equal to 5mm, 8mm and 11mm.

578 (a)

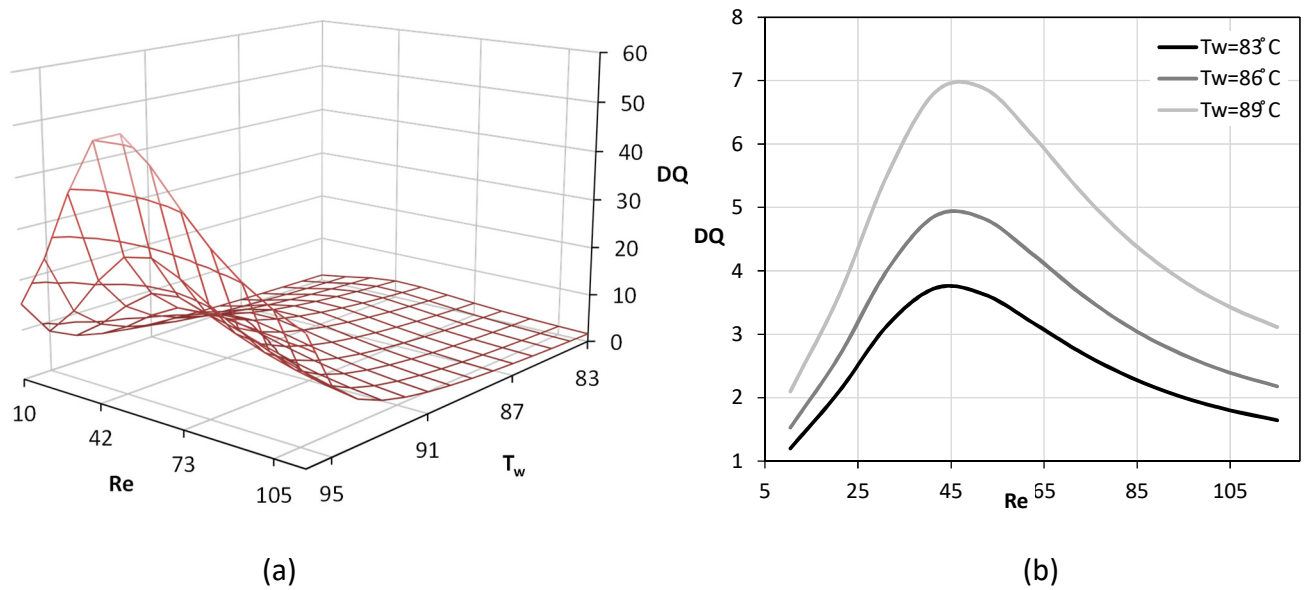

579 (b)

580 **Figure 13 Dimensionless parameters  $DQ$  as a function of film Reynolds number and tube outer**  
 581 **radius [mm] at heat transformer representative conditions,  $T_w=83.0^\circ\text{C}$ ,  $\omega_{in}=60\%$ ,  $T_{in}=97.1^\circ\text{C}$ ,**  
 582  **$P=12.5\text{kPa}$**

583 Similarly to  $DA$ , the maximum value of  $DQ$  is roughly constant, but for increasing tube radii, the  
 584 optimal Reynolds number increases as well (Figure 13). According to this criterion, for the heat  
 585 transformer application case, Reynolds number of 30, 40 and 55 maximise heat transfer in the  
 586 absorber (or minimize the process irreversibility), respectively, when the tube radii equal to 5mm,  
 587 8mm and 11mm. Moreover, the value of Reynolds which maximizes  $DQ$  is weakly influenced by the  
 588 temperature difference between the inlet and the wall temperature, as shown in Figure 14 for  
 589 different wall temperatures.  $DQ$  increases relentlessly when the wall temperature is augmented (i.e.

the temperature difference between the inlet solution value and the wall is lowered) for a fixed Reynolds number (Figure 14a).

**Figure 14 Dimensionless parameters  $DQ$  as a function of film Reynolds number and tube wall temperature at heat transformer representative conditions,  $r=9\text{mm}$ ,  $\omega_{in}=60\%$ ,  $T_{in}=97.1^\circ\text{C}$ ,  $P=12.5\text{kPa}$**

When the assumption of thermodynamic equilibrium of the inlet solution is relaxed and a  $2^\circ\text{C}$  sub-cooling is introduced consistently with the calculation performed for the chiller application, the maxima move to slightly higher Reynolds (Figure 15). Also, the influence of the wall temperature is intensified and higher  $T_w$  are associated to increasing Reynolds. More significantly, an optimal  $DQ$  condition can be shown with respect to  $T_w$  and Reynolds for the heat transformer;  $0.035\text{kg}\cdot\text{m}^{-1}\text{s}^{-1}$ ,  $T_w=92^\circ\text{C}$  (Figure 15a). In this circumstance the optimal wall temperature is minimized and the optimal Reynolds is maximized ( $Re=71$ ). The behaviour of the previously defined objective function  $DQ$  with respect to Reynolds and the tube outer radius for a sub-cooled solution is similar to the case of an inlet solution at thermodynamic equilibrium with the vapor in the absorber, hence, is not represented herein.

**Figure 15 Dimensionless parameters  $DQ$  as a function of film Reynolds number and tube wall temperature at heat transformer representative conditions, 2°C sub-cooling inlet solution,  $r=9\text{mm}$ ,  $\omega_{in}=60\%$ ,  $T_{in}=95.1^\circ\text{C}$ ,  $P=12.5\text{kPa}$**

When both  $T_w$  and  $T_e$  are fixed and the sub-cooling of the inlet solution becomes a parameter, a best value of the latter can be identified (Figure 16). Up to that value, higher sub-cooling at the inlet move the optimal condition to lower wall temperatures and higher Reynolds. By referring to the physical meaning of this parameter and the different operability of the absorber in the heat transformer application case considered, while maximising  $DQ$ , ceteris paribus for the operative conditions other than the absorber, the whole systems operate at its highest COP and best thermodynamic state. This condition corresponds to the maximum thermal power supplied by the heat transformer at high temperature for the least irreversibility introduced by the absorber.

**Figure 16 Dimensionless parameters DQ as a function of film Reynolds number and solution sub-cooling at heat transformer representative conditions,  $r=9\text{mm}$ ,  $\omega_{\text{in}}=60\%$ ,  $T_w=83.0^\circ\text{C}$ ,  $T_e=97.1^\circ\text{C}$ ,  $P=12.5\text{kPa}$**

## 5. Conclusions

The LiBr-H<sub>2</sub>O concentration and temperature distribution inside the laminar falling film have been obtained from the numerical solution of the coupled system of species and energy transport equations. Velocity, temperature and concentration fields, in turn, allow estimating the gradients and fluxes of these variables and, finally, the local volumetric entropy generation of an absorptive film flowing over a cooled horizontal tube. From the general expression obtained, various entropy generation groups, distinguished in regard to different entropy variations sources, have been identified and investigated with respect to the critical parameters at play. This analysis characterises the irreversibility of the process occurring in real absorbers and has been used to identify the least irreversible value of the solution mass flow rate for various operative conditions. These results make evidence of the importance to work at reduced mass flow rates with a thin uniform film, and consequently, tension-active additives are required to realize this condition.

636 Furthermore, a simplified and general thermodynamic analysis of the whole system performance has  
637 been proposed in order to highlight the important role of irreversibilities  $\sigma$ . This analysis makes  
638 evidence of a dimensionless ratio " $Q/\sigma T$ " that separates the weight of the irreversibilities. By  
639 maximizing this term the system efficiency is enhanced. Since the duty of the absorber is different in  
640 refrigeration or heat boosting applications, two different dimensionless parameters have been  
641 defined,  $DQ$  and  $DA$ , comparing, respectively, thermal flux at the tube wall and absorption at the  
642 interface with entropy generation related to the process.

643 The following main conclusion can be stated:

- 644 - The parametric analysis performed makes evidence that a minimum entropy generation can  
645 always be identified in terms of the film Reynolds number.
- 646 - The absorber of a chiller and that of a heat transformer work in different operative conditions  
647 which determine different irreversibility amounts introduced. In general, entropy generation  
648 in the heat transformer operative conditions is lower than that of the chiller and, although  
649 the overall trend is conserved, the minima occur at higher Reynolds.
- 650 - A bigger radius increases the absolute value of every entropy generation group. Thermal  
651 irreversibility  $E_t$  highlights a relaxingly-increasing trend with respect to Reynolds number.  
652 Contrarily, the vapor diffusion related irreversibility  $E_d$  is characterised by a relentlessly  
653 decreasing trend. The group related to the coupled effects of mass convection and heat  
654 transfer  $E_c$  has a critical effect on the global trend of the entropy generation rate per unit  
655 length  $E_G$  and shows a local minimum, which can be explained considering that, increasing  
656 Reynolds number, the velocity field is intensified while absorption heat release is reduced. A  
657 bigger outer radius moves the minimum to higher  $Re$  and to lower values of  $E_c$ . Finally, the  
658 bigger the tube radius the higher the friction related irreversibility  $E_f$ .

- Comparing chiller and heat transformer applications, as a rule, the latter highlights a higher impact of the diffusion related irreversibility.
- A higher difference between the solution inlet and tube wall temperatures increases both heat transfer and, increasing the driving force for vapor absorption, mass transfer at the interface. Accordingly, entropy generation is higher when this temperature difference is increased, while the optimal Reynolds is weakly dependent on this parameter.
- When the inlet solution is at thermodynamic equilibrium with the vapor pressure in the absorber, heat transfer at the wall and mass transfer at the film interface (represented through the dimensionless parameters  $DQ$  and  $DA$ ) can be maximised by a defined value of film Reynolds number. It can be highlighted that the optimal value of this parameter is mainly dependent on the outer tube radius and the application case (i.e chiller or heat transformer operability), while a weak influence of the temperature difference between the inlet and the wall temperature is shown.
- The sub-cooling of the solution moves the occurrence of the maxima to higher Reynolds. Contrarily to the case of thermodynamic equilibrium, when the temperature difference between the inlet and the wall temperatures is changed,  $DQ$  and  $DA$  display the occurrence of an optimal condition and higher values of the sub-cooling move the maximum to lower wall temperatures and higher Reynolds. Furthermore, by considering the physical meaning of each parameter and the different operability of the absorber in the two application cases considered, it can be observed that the optimal value of  $DA$ , at which the absorber operates at the maximum absorption rate with the least thermal power to be rejected, corresponds to the most suitable condition for a chiller or a heat pump, while by maximising  $DQ$  in the absorber the maximum thermal power is supplied at high temperature and, consistently, a heat transformer operates at its best thermodynamic condition.

683 In conclusion,  $DQ$  and  $DA$  practically allow the user to realise a second law optimization of the  
684 absorber performance with respect to Reynolds, tube radius and cooling water temperature, by  
685 taking into account entropy generation. Also their influence on the overall system performance has  
686 been suggested.
