Dataset link: [Data on the juvenile products of the Upper Pumice eruption on Nisyros \(Braschi et al., 2022\)](#) (Original data)

ABSTRACT

This data article includes the description and the geochemical and mineralogical dataset of 67 pyroclastic rock samples from the Upper Pumice (UP) explosive activity of Nisyros volcano (eastern South Aegean Active Volcanic Arc). A detailed field and petrographic description of the studied outcrops and samples are reported, including representative photomicrographs and SEM images, whole-rock major and trace elements compositions of 31 representative samples and Sr-Nd isotope ratios on 22 selected samples. Analytical methods and conditions used for data acquisition are also reported. The UP eruption produced a stratigraphic sequence constituted by a basal fallout deposit, gradually substituted by pyroclastic density current (PDC) deposits; these are overlaid by a lag-breccia unit, and the sequence is closed by a grey ash flow level. The juvenile is mainly constituted by

Please cite this article as: F. Mastroianni, E. Braschi and M. Casalini et al., Data on unveiling the occurrence of transient, multi-contaminated mafic magmas inside a rhyolitic reservoir feeding an explosive eruption (Nisyros, Greece), Data in Brief, <https://doi.org/10.1016/j.dib.2022.108077>

white-yellow, moderately crystalline pumice with rhyolitic composition and homogenous Sr-Nd isotope values. Variable amounts of dense, grey, crystalline juvenile lapilli clasts (CRC, Crystal-Rich Clast), with rounded shape and less evolved composition (andesite to dacite) are also present in the deposit. These mafic CRCs are peculiar due to their large variability in textures (from distinctive diktytaxitic to strongly fragmented structure without a defined fabric) and in the geochemical and isotopic composition.

The data acquired were fundamental to reconstruct the complex and peculiar history of ascent, storage and differentiation/assimilation processes of these mafic melts before their intrusion into the shallow, rhyolitic magma chamber, with important implication on the possible eruption trigger during the more recent explosive phase of activity at Nisyros volcano. Moreover, the geochemical and isotopic analyses provide new original data to the general knowledge of the Aegean volcanics.

All the data reported in this paper are related to the research article Braschi et al.

1 Specifications Table

Subject area	Earth and Planetary Sciences
Specific subject area	Geochemistry and Petrology
Type of data	Text files, pictures, tables and graphs.
How data was acquired	Field work: detailed sampling and deposit description during two field campaigns. Petrographic analyses through polarized light microscopy. Image acquisition through scanning electron microscope (SEM). Laboratory measurements: Sr isotope composition through Thermal Ionization Mass Spectrometry (TIMS) and Nd isotope composition through Multicollector Inductively Coupled Plasma Mass Spectrometry (MC-ICP-MS). Major and minor composition of mineral phases through Electron Microprobe Analysis (EPMA).
Data format	Raw and analysed
Description of data collection	All data are originals and were collected by the authors using accepted procedures and robust analytical condition. Details of data collection are reported in the "Experimental Design, Materials, and Methods" section.
Data source location	Institution: Istituto di Geoscienze e Georisorse, Sezione di Firenze; Dipartimento di Scienze della Terra, Università degli Studi di Firenze. City/Town/Region: Firenze Country: Italy Latitude and longitude (and GPS coordinates, if possible) for collected samples/data: 36.58905° N, 27.16918° E Nisyros Island, Dodecanese, Greece
Data accessibility	Repository name: EarthChem Library Data identification number (permanent identifier, i.e. DOI number): DOI: 10.26022/IEDA/112.230 . Direct link to the dataset: https://ecl.earthchem.org/view.php?id=2230 .
Related research article	E. Braschi, F. Mastroianni, S. Di Salvo, M. Casalini, S. Agostini, G. E. Vougioukalakis, L. Francalanci, Unveiling the occurrence of transient, multi-contaminated mafic magmas inside a rhyolitic reservoir feeding an explosive eruption (Nisyros, Greece), <i>Lithos</i> 410–411 (2022) 106,574. https://doi.org/10.1016/j.lithos.2021.106574

2 Value of the Data

- These data are crucial for the reconstruction of the plumbing system dynamic of Nisyros Volcano before the Upper Pumice eruption.
- The data, including mineral chemistry and Sr-Nd isotope ratios, expand and integrate the existent database of volcanic products of the South Aegean Active Volcanic Arc.
- Crystal-rich clasts (CRC) show the lowest $^{143}\text{Nd}/^{144}\text{Nd}$ values recorded for the Nisyros-Kos-Yali volcanic field.
- The data will contribute to a better understanding of the involvement of different crustal components and ascent pathways of mafic magmas below active volcanoes in subduction zones.

12 1. Data and Images

13 Data, images and figures here reported were interpreted and discussed in Braschi et al. [1] to
14 unravel the origin and evolution of the mafic components erupted by the UP activity, and their
15 interaction with the main rhyolitic host magma. The full dataset of major, trace elements and Sr-
16 Nd isotopes on whole rocks, together with glass composition and mineral chemistry is available
17 in the EarthChem Library repository at <https://doi.org/10.26022/IEDA/112230>.

18 1.1. Field observation

19 **Table 1** is a list of the samples collected from the Upper Pumice (UP) deposit. The table
20 reports detailed information of the sampling locations for the different outcrops (see also **Fig.**
21 **1**), including the type of depositional unit. A schematic petrographic description of each sam-
22 ple is also reported including their structure, paragenesis and texture features. Some samples
23 have been subdivided into different portions according to their characteristics and labelled with
24 different letters.

25 Representative photos of the sampled outcrops of the UP deposit are shown in **Figs. 2–8**
26 and illustrate in detail the different depositional units emplaced by the UP eruption and their
27 juvenile components.

28 **Figs. 9–12** report selected representative images of cut blocks of samples and hand-specimen
29 highlighting the difference between the two main lithotypes (pumice and crystal-rich clasts,
30 hereafter CRCs) and within the CRC population itself. The CRCs show wide variation in their
31 vesiculation and colour; the latter is due to the different proportion of crystal content (both for
32 phases and size) and groundmass, varying from grey to white.

33 1.2. Petrography

34 In the next section, a detailed selection of microphotographs and backscattered (BSE) images
35 (**Figs. 13–22**) are reported to show the main petrographic characteristics of the studied samples
36 (pumices and CRCs).

37 Pumices from all the deposits have similar features. They are porphyritic, mainly composed
38 by a glassy matrix and a crystal content up to 5–10%; vesicularity vary between 30% and 50%;
39 the matrix appears often fibrous or fluidal. Paragenesis is mainly composed by plagioclase (al-
40 ways more than 75%), orthopyroxene and amphibole; clinopyroxene and olivine are rare; acces-
41 sory phases are oxides and apatite, often included in orthopyroxene. Crystals are often found as
42 glomeroporphyritic aggregates. Plagioclase phenocrysts sometimes show disequilibrium textures,
43 with sieved cores, resorbed zones, resorbed or overgrowth rims.

Table 1

Location and petrographic description of the studied samples from the Upper Pumice deposit (Nisyros, Greece). *Footnotes:* * samples with mingling evidences are doubled to describe crystal-rich and pumiceous portions: "-" thin section not available. CRC: Crystal-rich clast; Plg: plagioclase; Cpx: clinopyroxene; Opx: orthopyroxene; Amph: amphibole; Ol: olivine; Ox: oxides; ph: phenocrysts (crystals >0.5 mm); mph: micro-phenocrysts (crystals >0.3 mm). Reaction rims: presence of olivines and/or opx with reaction rims to amphiboles; ph+mph in CRC (%): estimated abundance of crystals coarser than the average size of the microcrystalline groundmass in the CRCs.

*Samples with mingling features are doubled to describe crystal-rich portions and pumiceous portions; "-" thin section not available

CRC: Crystal-rich Clast; Plg: plagioclase; Cpx: clinopyroxene; Opx: orthopyroxene; Amph: amphibole; Ol: olivine; Ox: oxides; ph: phenocrysts (crystals >0.5 mm); mph: micro-phenocrysts (crystals >0.3 mm). Reaction rims: presence of olivines and/or opx with reaction rims to amphiboles; ph+mph in CRC (%): estimated abundance of crystals coarser than the average size of the microcrystalline groundmass in the CRCs.

Fig. 1. Location of the collected samples.

44 Crystal-rich clasts are highly heterogeneous in textures and were subdivided in three groups,
 45 named Type-A, Type-B and Type-C. The paragenesis is similar between the three groups: pla-
 46 gioclase represents more than 50% of the mineral assemblage, followed by amphibole and py-
 47 roxenes; olivine is rare; accessories phases are oxides and apatite. Amphibole can be found as-
 48 sociated with plagioclase to form the microcrystalline groundmass network, either with acicular
 49 or tabular habitus, or as reaction rims on pyroxenes. Rare amphibole and pyroxene phenocrysts
 50 can be up to 2 mm, while plagioclase phenocrysts can reach 6 mm.

51 Type-A clasts are mostly found in fallout deposits and are characterised by microcrystalline
 52 texture with almost equigranular crystal size (0.1–0.5 mm), constituted by tabular plagioclases,
 53 amphiboles and pyroxenes (mainly orthopyroxene), with variable oxides content. Crystals are
 54 dispersed in a glassy, highly vesiculated groundmass, without a defined fabric.

55 Type-B clasts are the more variable in terms of crystal content and size; they show micro-
 56 crystalline, inequigranular, low porphyritic texture, with variable crystal orientation defining at
 57 places a sort of network, likely the Type-C textures. They are present both in the fallout and
 58 lag-breccia deposits.

59 Type-C clasts are mostly found in the lag-breccia deposits, and they are characterized by a
 60 equigranular, low porphyritic textures with diktytaxitic voids, formed by a network of acicular
 61 plagioclases and amphiboles, with interstitial pyroxene. They show interstitial glass and variable
 62 vesicle abundance, generally lower than the other two types.

63 1.3. Geochemistry

64 The following table (Table 2) reports the complete dataset of major and trace element data
 65 on 31 whole-rock samples of pumice and CRCs of the Upper Pumice activity. Selected incompat-

Table 2

Major and trace element composition and Sr-Nd isotopic ratios of the studied samples from the Upper Pumice deposit (Nisyros, Greece). *Footnotes:* Major and trace elements data were performed at the Actalbas Laboratory (Ancaster-Ontario, Canada). Sr Isotope ratios were determined by TIMS Thermo-Finnigan Triton-Ti at the Radiogenic Isotope Laboratory of the Department of Earth Sciences, University of Florence. Nd isotope data were performed at the Radiogenic Isotope Laboratory of the IGG-CNR of Pisa by MC-ICPMS Thermo-Finnigan Neptune-Ti. * Major elements were analysed at the Department of Earth Sciences of the University Florence by XRF and trace elements were analysed at the Department of Earth Sciences of the University of Perugia by ICP-MS (see [8] for analytical details). Italic labels: trace elements analysed by XRF at the Department of Earth Sciences of the University of Florence (see [6] for analytical details). La/Sm and Tb/Yb ratios are normalised to chondritic values. nd= not determined; bdl= below detection limit; 2se: 2 standard error of the mean.

Major and trace elements data were performed at the Actlabs Laboratory (Ancaster-Ontario, Canada). Sr Isotope ratios were determined by TIMS Thermo-Finnigan Triton-Ti at the Radiogenic Isotope Laboratory of the Department of Earth Sciences, University of Florence. Nd isotope data were performed at the Radiogenic Isotope Laboratory of the IGG-CNR of Pisa by MC-ICPMS Thermo-Finnigan Neptune-Ti. * Major elements were analysed at the Department of Earth Sciences of the University Florence by XRF and trace elements were analysed at the Department of Earth Sciences of the University of Perugia by ICP-MS (see [6] for analytical details). Italic labels: trace elements analysed by XRF at the Department of Earth Sciences of the University of Florence (see [6] for analytical details). La/Sm and Tb/Yb ratios are normalised to chondritic values. nd= not determined; bdl= below detection limit; 2se: 2 standard error of the mean.

Fig. 2. Images of the paleosol horizon marking the base of the UP pyroclastic sequence (a detail is showed in the inset) and the contact with the deposit of the previous Lower Pumice (LP) explosive eruption.

66 ible trace elements and Rare Earth Elements (REE) together with Sr-Nd isotope ratios were also
 67 determined on a further selection of 22 samples.

68 The pumices are rhyolites ($\text{SiO}_2 > 70 \text{ wt.}\%$) belonging to the high-K calc-alkaline series,
 69 whereas the CRC show an affinity with the calc-alkaline series, ranging from basaltic ande-
 70 site/andesite to dacite (SiO_2 between 56 and 64 wt.%). Loss on ignition (LOI) is always lower
 71 than 2% in the CRCs, while it is up to 5.3% in the pumices.

72 REE and incompatible element patterns (Figs. 23 and 24) are typical for subduction-related
 73 calc-alkaline rocks. REE values are normalised to the chondrite data, while incompatible ele-
 74 ments are normalised to the primordial mantle values [9]. Symbols used in the graphs are the
 75 same used in Braschi et al. [1]: purple symbols represent samples from the fallout deposit, the
 76 green ones are samples from the lag-breccia deposit and those from PDC units are black; open
 77 diamonds represent pumices, CRCs have different symbols for each texture typology (circles for
 78 Type-A, triangles for Type-B and squares for Type-C).

Fig. 3. Selection of representative images of the basal fallout unit (Unit-A) outcropping in the northern part of the caldera rim (outcrop 1) near the Emborion village. (A) schematic map of the UP distribution together with the location of the different sampling site (see legend for detail); (B) main view of the outcrop 1. The Unit-A consists in a 0.5 to 8 m thick level of unconsolidated, granular sustained, moderately assorted, massive fallout, mainly composed of white sub-angular pumices, with size varying from lapilli to small blocks and dense Crystal-rich Clasts (CRC) (C). Occasional evident stratification, formed by layers of clasts at different grain size, is observed (D) and interpreted as the result of syn-depositional reworking in the most proximal deposits [2-4].

Fig. 4. Representative images of the basal fallout unit (Unit-A) outcropping in the northern part of the caldera, just inside the rim border (outcrop 4) (A) and along the main road, near the coast above Pali village (outcrop 5) (C). Pumices are the prevalent juvenile components whereas CRCs constitute about 5% of the deposit. The lithic content is less than 2%, there are very small quantities of fine ash and loose crystals as matrix. This unit has been interpreted as pyroclastic fall deposit, emplaced from the column of a Plinian or sub-Plinian eruption [2,3,5]. The schematic map of the UP distribution and outcrops location is also reported (B).

Fig. 5. Representative image of outcrop 6 where the fallout unit is particularly well preserved (A). CRCs clasts are evident within the pumices showing grey colour and globular shapes (C). The schematic map of the UP distribution and outcrops location is also reported (B) (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article).

Fig. 6. Representative image of the second unit (Unit-B) at the contact with the overlying Unit-C, close to outcrop 7, along the main road to Cape Katsouni, in the north-east part of Nisyros. Unit-B is a succession of several layers of fully diluted pyroclastic current (according to [6]) alternated with fallout levels. The flow levels are formed by a matrix of ash and loose crystals where sub- to well-rounded pumice lapilli are immersed, alternating with layers of coarser ash. Unit-C is a massive deposit of unconsolidated material, composed of coarse ash, fine lapilli and loose crystals, with well rounded, slightly vesiculated pumice and dispersed lithic clasts [2], interpreted as a granular fluid-based current (according to [6]).

Fig. 7. Representative image of the principal outcrop of unit-D exposed on the main street south of Cape Katsouni (outcrop 8). Unit-D is a dense pyroclastic current, gradually interlayered toward the top with lithic-rich lenses. This unit is constituted by a breccia deposit composed of rounded pumices and abundant (up to 15%) dense juvenile clasts with crenulated or "bread crust" surfaces, up to few tens of centimetres in diameter, and angular lithic clasts within an unconsolidated ash matrix including. Lithics mainly consist of fresh and hydrothermalised lava clasts; fragments of hypoabyssal igneous rocks, skarn and limestone with hydrothermal alteration are also present [as also reported by 2, 3]. Unit-D is interpreted as a lag-breccia deposit [2], emplaced from a dense PDC formed by the collapse of the eruptive column as a consequence of the caldera collapse [7].

Fig. 8. Image of the top unit of the UP sequence (Unit-E) composed by a massive or weakly laminated deposit formed by grey ash with loose crystals, rounded centimetre-sized pumice and lithic lava and limestone clasts (about 20%, [2]). This unit have been interpreted as a deposit from diluted pyroclastic density currents [2] or due to a phreatomagmatic eruptive event [5].

Fig. 9. Cut blocks of pumice samples collected in different outcrops from the fallout deposit (A: NIS353; B: NIS374; C: NIS377) and from the lag-breccia deposit (D: NIS418; E: NIS419, outcrop 8). Pumices from the PDC deposits collected in outcrop 9 are also shown (F: NIS431; G: NIS433). Pumice clasts are white or pale yellow in colour, porphyritic and highly vesiculated, sub-angular, and range from 10 to 40 cm in diameter. Pumices often include micro-enclaves or grey bands (E, F) (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article).

Fig. 10. Cut blocks of representative CRC samples of the collected from the fallout deposits. A: NIS356; B: NIS357; C: NIS359; D: NIS358; E: NIS370; F: NIS371; G: NIS378; H: NIS381. See Table 1 for details.

Fig. 11. Cut blocks of representative CRC samples collected from the lag-breccia deposits (outcrop 8). A: NIS426; B: NIS425; C: NIS423; D: NIS416; E: NIS424; F: NIS427; G: NIS421. See Table 1 for details.

Fig. 12. Representative photos of two samples showing the contacts between pumice and CRCs. The contact between the two lithologies are sharp but convoluted due to a process of plastic interaction.

Fig. 13. Comparison between hand-specimen blocks and the relative microphotographs acquired on the thin section, showing the three different textures types defined among the CRC samples.

Fig. 14. Cut block sample and the relative microphotograph detail of the contact between pumices and a dense crystal-rich clast. The dispersion of CRC portions into the pumice is evident both as loose crystals and micro-encalves.

Fig. 15. Thin section microphotograph of Type-A CRCs. A: NIS356, parallel and crossed nicols; B: NIS 356, detail of crystal cloth (B.1); C: NIS 371; D: NIS 378 with a resorbed olivine phenocryst (parallel nicols).

Fig. 16. BSE images of Type-A CRC obtained by SEM. A: NIS317; B and C: NIS368d; D: NIS420.

Fig. 17. Thin section microphotograph of Type-B CRCs. A: NIS314, crystal-cloth presence; B: NIS423, parallel and crossed nicols, plagioclase phenocryst with sieved texture; C: NIS360, parallel and crossed nicols.

Fig. 18. BSE images of Type-B CRCs from the fallout deposit obtained by SEM observation. A: NIS357; B: NIS 368b; C: NIS364; D: NIS318.

Fig. 19. BSE images of Type-B CRCs from lag-breccia deposit obtained by SEM observation. A: NIS424; B and C: NIS430.

Fig. 20. Thin section microphotograph of Type-C CRCs. A: NIS422, parallel nicols detail of diktytaxitic texture and olivine with reaction rim (A.1); B: NIS421, parallel nicols detail of diktytaxitic texture and crystal cloths (B.1). D: detail of olivine with reaction rim.

Fig. 21. Examples of the grain size variations within the Type-C samples. From the top: A, NIS421, B, NIS422; middle: C, NIS426, D, NIS427, E, NIS313; bottom: F, NIS312.

Fig. 22. BSE images of Type-C CRC samples obtained by SEM observation. A: NIS379b; B: NIS422; C: NIS428.

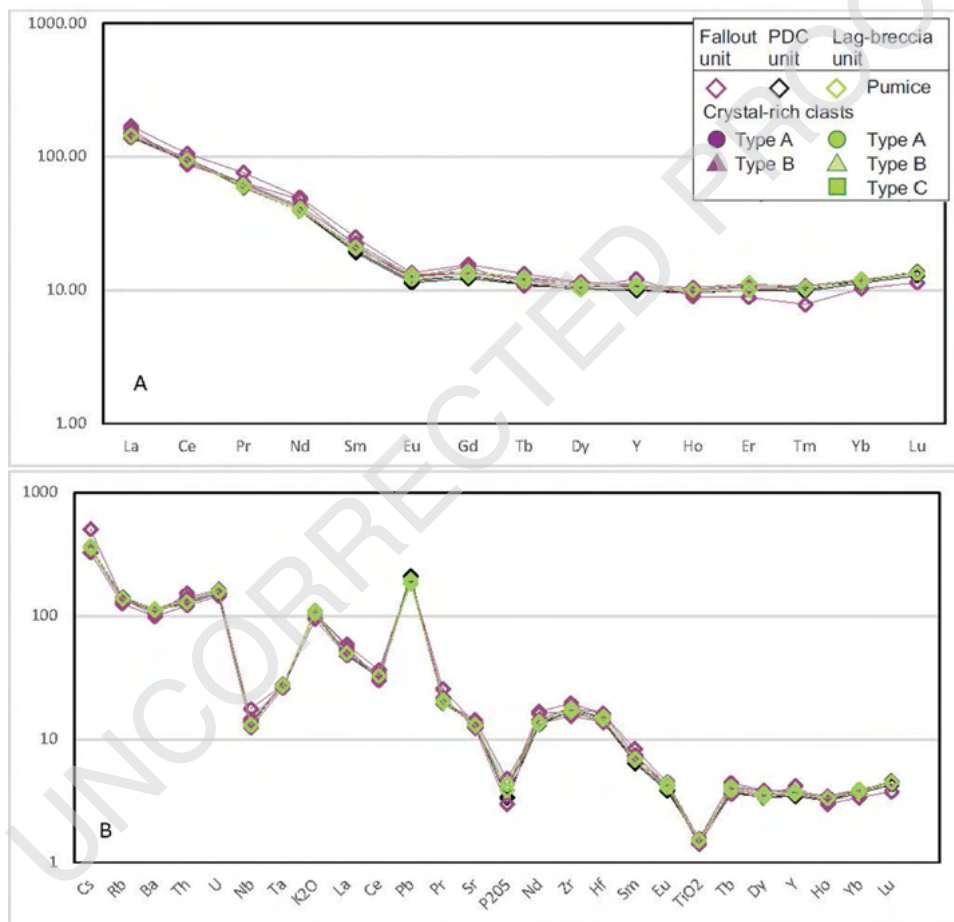

Fig. 23. REE (A) and incompatible element (B) patterns of pumice samples.

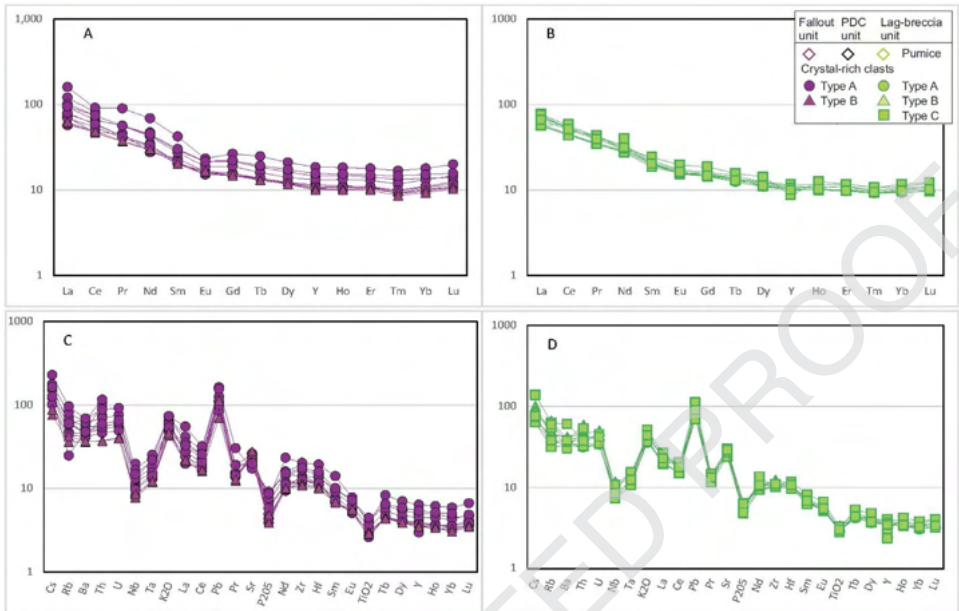

Fig. 24. REE (A and B) and incompatible element (C and D) patterns of CRC; A and C are samples from fallout and PDCs deposits, B and D are samples from lag-breccia deposits.

79 1.4. Mineral chemistry

80 *In situ* investigation of crystal chemistry was also performed on 10 selected samples of
 81 pumices and CRCs to explore the minerals and glass compositional variability. The following
 82 tables (Tables 3–7) report a representative selection of the mineral chemistry composition for
 83 plagioclases, pyroxenes, amphiboles and oxides, as well as the composition of glasses.

Table 3

Representative major and minor element composition of glasses on selected samples from the Upper Pumice deposit (Nisyros, Greece). *Footnotes*: The composition of glassy groundmasses was obtained with a Jeol JXA 8600 superprobe at the CNR-IGG in Florence. bdl= below detection limit.

The composition of glassy groundmasses were obtained with a Jeol JXA 8600 superprobe at the CNR-IGG in Florence. bdl= below detection limit

Table 4

Representative plagioclase composition (wt.%) on selected samples from the Upper Pumice deposit (Nisyros, Greece). Plagioclase crystals analysed in the pumice samples are generally more albitic (ca. 30 % An) than those in CRCs (>60 % An). *Footnotes:* gdm=crystal size <0.5 mm. Ab= Albite, An= Anorthite; Or= Orthoclase.

Footnotes: gdm=crystal size <0.5 mm. Ab= Albite, An= Anorthite; Or= Orthoclase.

Table 5

Representative pyroxene composition (wt.%) on selected samples from the Upper Pumice deposit (Nisyros, Greece). The pyroxenes are mostly orthopyroxenes; clinopyroxenes are less common and are generally found as microcrystals or in aggregates. *Footnotes:* cpx: clinopyroxene; opx: orthopyroxene; bdl = below detection limit; En = Enstatite; Fe = Ferrosilite; Wo = Wollastonite; Mg#: molecular Mg/(Mg+Fe+Mn).

84 2. Experimental Design, Materials and Methods

85 The field work was carried out with a special care in sampling all of the different juveniles
86 characterising each outcrop of the Upper Pumice deposits. A total of 67 samples (Table 1) was
87 collected during two field campaigns in 2006 and 2014.

88 Pumices were sampled from each location with the aim to investigate the possible variability
89 within the evolved juvenile component for a total of 16 samples (Fig. 1). The CRCs were also
90 sampled in detail, collecting 51 samples, according to their evident textural and physical vari-
91 ability (i.e., density, colour, crystal content) to explore their recurrence and distribution among
92 the different outcrops.

93 During preparation all specimens were cut in order to remove altered portions, then grinded
94 and powdered in an agate mill.

95 Major and trace elements were analysed by Actalabs Laboratories (Ontario, Canada) using the
96 LithoGeochemistry-4LithoResearch analytical package. The procedure consists in a lithium metabo-
97 rate/tetraborate fusion digestion and analyses are carried out using ICP-OES for major elements
98 and ICP-MS for trace elements (see www.actlabs.com). Accuracy and precision for major ele-
99 ments are estimated as better than 3% for Si, Ti, Fe, Ca, and K, and 7% for Mg, Al, Mn, Na; for
100 trace elements (above 10 ppm) they are better than 10%. REE, Rb, Sr, Y, Zr, Hf, Nb, Th, and U
101 were analysed.

102 Selected powdered samples were processed in an ultraclean laboratory environment (class
103 1000) at the Department of Earth Sciences of the University Florence. They were preliminarily
104 treated with 2 mL diluted 1 N HCl in an ultrasonic bath for 15', twice, then rinsed three times
105 with Milli-Q water to minimise isotopic variation induced by superelement processes that could
106 overprint the magmatic signature (e.g. [12] and references therein). After that they were pro-
107 cessed using the standard digestion technique described in [13] consisting in a sequential ad-
108 dition of concentrated HF and HNO₃ (in proportion of 4:1) of suprapure quality, followed by a
109 double addition of concentrated HNO₃, and subsequently by some 10 mL of diluted 6 N HCl and
110 placed on a hot plate at 140°. Cation-exchange AGW and Ln-spec reusable resins were used for
111 Sr, REE and Nd purification respectively, by sequential addition of properly diluted HCl suprapure
112 acid, as described in Avanzinelli et al. [13].

113 Sr isotope ratios were determined at the Department of Earth Sciences of the University
114 Florence using the Thermal Ionization Thermo-Finnigan Triton-TI mass spectrometer (TIMS),
115 equipped with nine collectors coupled with nine exchangeable amplifiers. For measurements
116 with the thermal ionization mass spectrometer, 100–150 ng of sample were loaded on single Re-
117 filament as nitrate form, with TaCl₅ and H₃PO₄ as activator and to keep the signal stable during
118 the analyses. ⁸⁷Sr/⁸⁶Sr were measured dynamically using the amplifier rotation method and cor-
119 rected using an exponential mass fractionation law to ⁸⁷Sr/⁸⁶Sr=0.1194. Each ratio is the average
120 of 120 measurements, to reach good precision (2σ) of the data. Within run, replicate measure-
121 ments of international NIST SRM 987 standard (0.710251 ± 0.000011 [13]) gave mean values of
122 ⁸⁷Sr/⁸⁶Sr = 0.710252 ± 0.000011 (2σ, n = 5) well comparable with those reported in literature
123 [14]. All errors reported are 2σ (2 standard error of the mean) for single data precisions and
124 2σd (2 standard deviation) for standards reproducibility (Table 8). The Sr analytical blank, mea-
125 sured during the course of the analytical session, is 60 pg, which is in agreement with blank
126 reproducibility of the lab.

127 Nd isotope ratios were measured in the Laboratory of Radiogenic Isotopes at the IGG-CNR of
128 Pisa using the new Thermo-Finnigan multicollector inductively coupled plasma mass spectrom-
129 eter (MC-ICP-MS) Neptune-Plus, equipped with a combined cyclonic and Scott-type quartz spray
130 chamber, Ni-cones, a MicroFlow PFA 100 μl/min self-aspiring nebuliser and a Teledyne Cetac
131 ASX-560 Autosampler. All samples were diluted in ultrapure 2% HNO₃ solution after digestion
132 and elemental separation. During Nd analyses, instrumental mass fractionation was corrected us-
133 ing the ¹⁴⁶Nd/¹⁴⁴Nd ratio (0.7219). Mass interference correction was performed using the ratios
134 ¹⁴⁷Sm/¹⁴⁴Sm (4.838710), and ¹⁴⁷Sm/¹⁴⁸Sm (1.327400). The analytical accuracy and reproducibil-
135 ity for the within run internal standard NdFi is 0.511460 ± 14 (2σ, n = 4), well comparable to

Table 8

Accuracy and reproducibility of Sr-Nd isotopes measurements on international and internal reference standards. Footnotes: 2se = 2 standard error of the mean; 2sd = 2 standard deviation.

the average value reported in [13] measured by TIMS. Long-term external reproducibility of the laboratory for $^{143}\text{Nd}/^{144}\text{Nd}$ on international reference material J-Ndi-1 was 0.512098 ± 5 (average of 17 replicates), which match well the reference values of [15], (Table 8).

A number of 10 samples were selected, on the basis of their textural and compositional representativeness, among the different juvenile types (pumices and CRCs) for mineral chemistry investigations on minerals and glasses. Analyses were performed by electron microprobe JEOL Superprobe JXA-8600 at the IGG-CNR of Florence. Working conditions were 15 kV of accelerating voltage and $10 \mu\text{A}$ of beam current. Beam diameter varied from 2 to $5 \mu\text{m}$ for mineral phases and 10 for glasses. Peak counting time was 15 sec for major elements, except for Na that is counted for 10 sec to minimize the alkali loss effect, and 40 sec for minor elements. Backgrounds were counted at specific positions for 5 and 20 sec on major and minor elements, respectively.

A set of natural phases (Astimex Albite, Olivine, Diopside, Orthoclase, Plagioclase, Sanidine, Kaersutite, Bustamite, Obsidian and Smithsonian Anorthite *Great Sitikin Islands*, Olivine *San Carlos*, Augite *Kakanui*, Pyrope *Kakanui*, Hornblende *Kakanui*, Ilmenite or Bio-Rad Albite and Orthoclase) and synthetic internal glass standards (ALV-47 and CFA-981) was used as primary and quality control standards. PAP software was used for correction [16]. Precision was within 1% for silica, 2–3% for other major elements and about 5–8% for minor elements.

Scanning Electron Microprobe (SEM) images were achieved at the MEMA laboratory of the University of Florence using 20 kV of acceleration voltage and 2 nA of probe current.

155 Declaration of Competing Interest

156 The authors declare that they have no known competing financial interests or personal rela-
157 tionships which have, or could be perceived to have, influenced the work reported in this article.

Data Availability

Data on the juvenile products of the Upper Pumice eruption on Nisyros (Braschi et al., 2022) (Original data) (Earth/Chem).

165 Acknowledgments

166 The authors sincerely thank all the researchers associated to the Radiogenic Isotopes Labo-
167 ratory of Florence and Pisa for assistance during analysis and isotope measurements. A special
168 thank to dott.ssa L. Chiarantini for assistance during SEM session. The financial support was pro-
169 vided by Italian MIUR through the PRIN-2017 funding grant 20178LPCPW, issued to LF.
