Keywords: 14 α -demethylase | antifungals | carbonic anhydrases | fungi | *Malassezia*

ABSTRACT

A novel series of compounds was designed and synthesized by combining the distal piperazine nitrogen of the antifungal ketoconazole (KTZ) with primary arylsulfonamides. The aim of this study is to present the basis for a new generation of *Malassezia* antifungal agents able to inhibit the enzyme lanosterol-14 α -demethylase (CYP51; EC 1.14.13.70) as well as a newly emergent therapeutic target: carbonic anhydrases (CAs; EC 4.2.1.1). The final compounds showed effective interactions with the intended targets in vitro, as well as KTZ comparable minimum inhibitory concentrations on yeast strains of the *Malassezia* genus: *Malassezia furfur* ATCC 14521; *Malassezia globosa* ATCC MYA 4612; and *Malassezia pachydermatis* DSM 6172. Overall, the data obtained account for the reported compounds as promising antifungal candidates with high safety profiles for the management of fungal infections.

1 | Introduction

Malassezia species (*spp.*) are high lipophilic yeasts symbiotically present as part of the natural microbiota on the skin of mammals particularly rich in sebum (i.e., in humans, the scalp, face, and chest among others) [1]. Any physical or physiological cause that disrupts the microbiota equilibrium may lead to *Malassezia spp.* overgrowth, which in turn triggers acute infections such as pityriasis versicolor, seborrheic dermatitis, dandruff, and folliculitis, among others [2, 3]. Such diseases may spread over the host surface as well as deeper within tissues with significant systemic effects when adequate pharmacological treatments are absent [2, 3]. *Malassezia spp.*, such as *Malassezia furfur*, *Malassezia globosa*, *Malassezia restricta*, and *Malassezia sympodialis*, are the most common yeasts on human skin [3]. In animals, *Malassezia pachydermatis* is the most represented yeast in the cutaneous mycobiome, both as a commensal and as a pathogen, and its

overgrowth is related to the onset of severe dermatitis and otitis externa in companion animals, mainly dogs and cats, and therefore assumes substantial clinical significance [4, 5]. The standard of care treatment of *Malassezia*-promoted infections largely depends on the specific clinical conditions, but more in general, any pharmacological approach accounts for the use of antifungal agents targeting the etiological yeast [1, 6, 7]. Representative drugs used for human and veterinary purposes are azole-containing derivatives shown in Figure 1, which are quite effective in inhibiting the cytochrome P450 14 α -demethylase enzyme (CYP51; EC 1.14.13.70). As a result, such compounds affect the conversion of lanosterol into ergosterol and compromise the specific lipidomic composition in yeast biomembranes.

Compounds such as ketoconazole (KTZ) and itraconazole (ITZ) contain multiple stereogenic centers and are therefore associated with extra costs of production and quality assurance. For instance,

in KTZ and ITZ, the triazolomethylene and aryloxymethylene moieties anchored to the dioxolane ring are always fixed in *cis* relation to each other, thus yielding the clinical formulation *cis*-(2*S*,4*R*)-(-) and *cis*-(2*R*,4*S*)-(+) enantiomers in a 1/1 ratio for the former [8] and *cis*-(2*R*,4*S*,2'*R*), *cis*-(2*R*,4*S*,2'*S*), *cis*-(2*S*,4*R*,2'*R*), and *cis*-(2*S*,4*R*,2'*S*) in a 1/1/1/1 ratio of four stereoisomers (two enantiomeric pairs) for the latter [9]. In addition, the clinical effectiveness of azole antifungals is constantly eroded by the long latency time necessary to establish reliable therapeutic responses, which, however, does not cope with the high variability of genomes and quick reproduction rates typical of fungi/yeasts [10, 11]. As a result, azole resistance leads to the constant growth of fungal-promoted infections in humans, animals, and plants and governs the need for more effective therapeutic tools [12]. In this study, we sought to make use of our know-how relative to the validation of the fungal-expressed metalloenzyme carbonic anhydrases (CAs, E.C. 4.2.1.1) target [13–17] by merging the prototypic primary sulfonamide CA inhibitory (CAI) moiety with a clinically used azole drug. The primary aim of our work is to explore the chemical feasibility of our strategy and to prove antifungal effectiveness, also in comparison to the parent drugs, of our final compounds. Specifically, we focused our attention on the chemically modifiable KTZ drug by adopting standard medicinal chemistry derivatization strategies.

2 | Results and Discussion

2.1 | Design and Synthesis of Compounds

We aimed to develop an efficient synthetic approach for obtaining KTZ-based CAI compounds through elongation of the antifungal molecular structure. For instance, we sought to make use of the unprotected piperazine distal nitrogen to establish covalent bonds with a variety of scaffolds incorporating the prototypic CAI moiety of the primary sulfonamide type [18]. For such purposes, the commercially available *cis*-(2*R*,4*S*)-(+) KTZ **1** enantiomer was deacetylated under basic conditions to afford the valuable synthetic intermediate **2** in a 91% yield on a multigram gram-scale reaction (Scheme 1).

All the final compounds reported in this study were obtained by direct coupling of **2** with ad hoc and freshly synthesized intermediates as reported in Schemes 2–4. (N.B. The synthesis and characterization of intermediates are reported in the Supporting Information file). In particular, the ureidic connection to afford **7**, **9a–d**, and **10a–b** was obtained by nucleophilic additions of **2** with the appropriate phenyl carbamates **3**, **5a–d**, and **6a–b**, respectively. On the other hand, the thioureido moiety in **24a–d**,

SCHEME 1 | Synthesis of the reactive ketoconazole intermediate **2**.

25, and **26** was positioned by reacting **2** with the corresponding isothiocyanates **20a–d**, **21**, and **22**, respectively (Schemes **2A,B**).

Additionally, we explored the synthetic feasibility of benzoxazolyl-containing compounds with the intent of

elongating the CAI-directed warhead by means of a valuable heteroaromatic scaffold. At first, intramolecular cyclization of the commercially available *ortho*-amino phenol **11** to afford the key derivative 2-oxo-benzoxazolyl **12** was operated, which in turn was exposed to carbon disulfide (CS₂) reaction conditions with

SCHEME 3 | Synthesis of intermediates **12** and **27**, and of the final compound **28**.

the intent of positioning the reactive 2-thioxo-moiety as in **27** (Scheme 3).

Although thionation attempts on **12** were unsuccessful, to our surprise, the desired intermediate **27** was obtained in a 64% yield by direct treatment of **11** with CS₂ and *N*-(3-dimethylaminopropyl)-*N'*-ethylcarbodiimide hydrochloride (EDC.HCl). Then, the final compound **28** was obtained in a 26% yield by the addition of **2** on **27** under basic conditions for triethylamine (Et₃N).

The nucleophilic features of **2** toward the halo-substituted benzyl/alkyl derivatives **30a–c**, **31a–c**, **32a–c**, **33**, and **34** yielded the final **35a–c**, **36a–c**, **37a–c**, **38**, and **39**, respectively, as shown in Scheme 4A.

The piperazine moiety in **2** was successfully investigated to perform 1,4-conjugate additions on acrylate intermediates **43a–b**, **44a–d**, and **45a–d** to yield **37b–c**, **48a–d**, and **49a–d**, respectively (Scheme 4B). It is noteworthy that derivatives **37b** and **37c** were obtained through both synthetic strategies in Scheme 4A,B with comparable recovery yields. Unfortunately, it was not feasible to obtain **50** under the various reaction conditions explored.

All the final KTZ-CAIs compounds reported herein were purified by silica gel column chromatography using the appropriate eluting mixtures, followed by trituration or recrystallization as needed (see Section 4). Full characterization was conducted by means of solution ¹H- and ¹³C-NMR. Elemental analyses account for a purity grade ≥ 96%.

2.2 | CA In Vitro Enzymatic Assay

All the final compounds were screened in vitro using the stopped-flow CO₂ hydration assay [19] to assess their inhibitory activity and selectivity profiles on the fungal β-CAs expressed

from the *Malassezia globosa* (MgCA), *Malassezia pachydermatis* (MpaCA), and *Malassezia restricta* (MreCA) genus. Human (h) CAs I, II, IX, and XII were assumed to be off-target isoforms. All the obtained data are reported in Table 1 as K_i values and are compared to the primary sulfonamide drug acetazolamide (AAZ) as the reference compound.

Overall, the data in Table 1 accounted for the hCA isoforms preferentially inhibited over the fungal ones from the panel of compounds reported in this study.

- i. Deeper insight revealed that ureido **7**, **9a–d**, and **10a–b** were slightly active toward MgCA, with K_is spanning between 3333 and 69497 nM. Conversely, the affinity for the remaining fungal β-CAs was increased up to medium nanomolar values. For instance, K_is for the MpaCA ranged between 291.6 and 4202 nM. A slight regioisomeric effect was observed for the **9a/9b** regioisomeric pair, with the 4-substituted being a 1.2-fold more effective inhibitor and almost equipotent to derivative **7** (i.e., K_is of 513.7 and 516.7 nM for **7** and **9b**, respectively). Elongation of the alkyl chain in **9b** up to two carbon atoms (i.e., **9d**) was beneficial for the inhibition potency, as the lowest inhibition value was obtained for the MpaCA among the ureido-containing compounds (i.e., K_i of 291.6 nM for **9d**). Significant regioisomeric effects on the kinetics were reported for the ureido derivatives **10a** and **10b**, respectively, with the latter being a 6.0-fold more effective MpaCA inhibitor when compared with its pair (K_is of 4202 and 702.1 nM for **10a** and **10b**, respectively). Similar values were obtained for the MreCA isoform (i.e., K_is between 206.2 and 892.6 nM). A strong regioisomeric effect was reported for **9a**, which inhibited the MreCA at a 90.5 nM concentration, and was thus 6.8-fold stronger than its 4-substituted counterpart **9b** (K_i of 613.9 nM). Replacement of the ureido moiety in **9a–d** with the thiourea instead, to afford **24a–d**, did not significantly affect the in vitro kinetic profiles for the fungal CAs. Again, MgCA

^aMean from three different assays, using the stopped flow technique (errors were in the range of ± 5 –10% of the reported values).

was the least inhibited, with K_i values ranging between 4482 and 8405 nM (Table 1). As for the MpaCA, a very slight regioisomeric effect was observed for **24c** and **24d** (K_i s of 604.2 and 610.9 nM, respectively), whereas elongation of the tether was far more evident on the kinetics as reported for **24a**, **b**, and **d** (K_i s of 4944, 841.7, and 610.9 nM for **24a**, **b**, and **d** respectively). A similar trend for **24a–d** was also reported on the MreCA, with K_i values spanning between 339.2 and 924.5 nM (Table 1). Further

elongation of the scaffold as in compounds **25** and **26** yielded K_i values for the fungal-expressed CAs in agreement with the compounds mentioned previously. Data in Table 1 clearly show that MgCA was poorly inhibited from both **25** and **26**, with K_i values of 6058 and 6027 nM, respectively. The same compounds showed good selectivity for the remaining fungal CAs. For instance, **25** was 2.6-fold more potent than **26** on the MpaCA (K_i s of 930.7 and 2390 nM, respectively), whereas the opposite trend,

although with lower intensity, was observed for the MreCA (K_i s of 620.6 and 338.2 nM, respectively). As for the benzoxazolyl-containing **28**, preferential inhibition for the MpaCA isoform over Mg- and MreCAs was reported (K_i s of 380.9, 4750, and 680.8 nM, respectively). Close inhibition potencies were obtained for derivatives **35a–c** on MgCA and were between 4604 and 4473 nM (Table 1). Elongation of the alkyl chain in **35a–c** yielded a progressive increase in the compound's effectiveness for the MpaCA isoform (i.e., K_i s of 803.3, 695.0, and 646.6 nM for **35a–c**, respectively). Marked effects on kinetics were reported for the same compounds on the MreCA, as the longest derivative **35c** was 2.1-fold more effective than its progenitor **35a**. A close matching trend was also obtained on comparison of **35c** with **35b** (K_i s of 701.7 and 318.3 nM for **35b** and **35c**, respectively). The introduction in **35a–c** of a sulfonyl-based connection as in **36a–c** induced high variability among the kinetic data in Table 1, although the preferential inhibition for the Mpa- and MreCAs was retained. Derivative **36b** was the most effective inhibitor for MgCA, with a K_i value of 4062 nM, thus being 1.3- and 1.5-fold more potent than **36a** and **36c**, respectively (i.e., K_i s of 5429 and 6124 nM for **36a** and **36c**, respectively). An identical kinetic trend was reported for the MpaCA isoform, although with limited differences (K_i s of 577.0, 559.7, and 677.9 nM for **36a–c**, respectively). As for the MreCA, compound **36a** was the most effective, with a K_i value of 288.2 nM. Derivatives **36b** and **36c** showed K_i s of 451.1 and 815.8 nM, respectively (Table 1). Among amido derivatives **37a–c**, high kinetic variability was reported. For instance, MgCA was inhibited in a concentration range spanning between 7435 and 5344 nM. Better results were obtained for the remaining fungal-expressed MpaCA and MreCA isoforms. Elongation of derivative **37a** to afford **37b** enhanced the inhibition potency by up to 6.7-fold (i.e., K_i s of 5391 and 891.7 nM, respectively). A strong regioisomeric effect was observed among **37b** and **37c** (i.e., K_i s of 891.7 and 1927 nM for **37b** and **37c**, respectively). As for the MreCA, elongation of the chain significantly reduced the inhibition potency by 1.7-fold (i.e., K_i s of 398.2 and 691.9 nM for **37a** and **37b**, respectively). Also, for this isoform, a strong regioisomeric effect was reported, as compound **37c** was 2.5-fold more effective inhibitor than its isomer **37b** (i.e., K_i s of 691.9 and 280.2 nM for **37b** and **37c**, respectively). Both derivatives **38** and **39** showed similar kinetic profiles for the fungal-expressed CAs and were all in agreement with the previously discussed compounds. Methoxy **39** was the most effective inhibitor for MreCA, with a K_i value of 390.5 nM (Table 1). Derivatives **48a–d** showed very few differences within each isoform. For instance, MgCA was inhibited in a concentration range of 5562–8036 nM, MpaCA was inhibited in a concentration range of 630.3–830.4 nM, and MreCA was inhibited in a concentration range of 403.5–472.4 nM, thus indicating that the substituents incorporated did not significantly affect the binding of the ligand within the catalytic cleft (Table 1). Quite interestingly, introduction of the 1,4-disubstituted diazepane moiety as in **49a–d** yielded better discrimination of the K_i values among the series (Table 1). Desymmetrization of the CAI-directed phenyl ring in **49a** to yield the

3-chlorophenyl derivative **49b** led to an 8.2-fold increase in the K_i associated value for the MgCA isoform (i.e., K_i s of 56446 and 6855 nM for **49a** and **49b**, respectively). The inhibition potency for MgCA decreased slightly by up to 1.2-fold by substitution of the chloro in **49b** with a fluorine instead to afford derivative **49c** (i.e., K_i s of 6855 and 8184 nM for **49b** and **49c**, respectively). Further improvement of the inhibition potency against MgCA was reported for the 3,5-difluorosubstituted derivative **49d**, which showed a K_i value of 4391 nM (Table 1). A different kinetic trend was reported for MpaCA, with **49a** being the most effective inhibitor, with a K_i value of 459.3 nM. All further manipulations on **49a** to afford **49b–d** induced a sequential increase of the MpaCA associated K_i values of up to 2583 nM (Table 1). As for MreCA, introduction in **49a** of chloro (**49b**) and fluoro (**49c**) halogens yielded opposite and equivalent effects on the ligand's inhibition potencies. As reported in Table 1, the former was more effective inhibitor by 1.2-fold and the latter was a less effective inhibitor by 1.4-fold when compared with unsubstituted **49a** (i.e., K_i s of 410.9, 337.3, and 470.2 nM for **49a**, **49b**, and **49c**, respectively).

- ii. Compounds reported herein were profiled in vitro on hCAs I, II, IX, and XII, and the data in Table 1 clearly accounted for the transmembrane CAs being preferentially inhibited over the constitutive and largely expressed I and II isoforms. Among ureido derivatives **9a–d**, the K_i associated values for the IX and XII isoforms were within the low nanomolar range (Table 1). The most effective hCA IX inhibitor was **9d**, with a K_i of 6.0 nM, whereas its shorter derivative **9c** was the most potent ligand for the XII isoform with a close matching K_i value (i.e., 6.4 nM). It is worth noting that all the 4-substituted arylsulfonamides **9b–d** showed similar potencies for hCA XII, whereas such a kinetic trend was not retained for the IX isoform (Table 1). As for the remaining isoforms, compounds **9a–d** were medium-high-nanomolar-range inhibitors. Also, in this case, compounds **9c** and **9d** were highly selective for hCA II and I, respectively (i.e., K_i s of 84.0 and 58.9 nM for hCA I and II, respectively). The introduction in **9a–d** of the thioureido ureido group, as in **24a–d**, significantly affected the kinetic trend among the hCAs tested, although preferential inhibition for the membrane IX/XII over the cytosolic I/II was retained. For instance, **24d**, which is the thioureido derivative of **9b**, was the most potent hCA IX inhibitor, with a K_i value of 4.4 nM, and all the remaining compounds were up to 10.8-fold less effective (i.e., K_i s spanning between 40.1 and 47.7 nM; Table 1). Closely matching K_i s were reported for **24b–d**, with values spanning between 8.0 and 9.2 nM, whereas derivative **24a** was a 72.5 nM hCA XII inhibitor. As for the hCAs I/II, compounds **24a–d** were high nanomolar inhibitors (Table 1). Insertion of the 1,4-triazolyl moiety as in **10a** and **10b** retained significant discrimination for hCAs I/II over IX/XII, with narrow differences in the K_i values due to the regioisomeric effect. It is worth noting that derivative **10b** was the most potent inhibitor of hCA XII, with K_i of 7.4 nM, and therefore close to the reference AAZ of 5.7 nM. Interestingly, SAR was reported for **25** and **26**. For instance, derivative **25** was selective for

the hCA XII isoform at a 9.0 nM concentration. A radical change in isoform selectivity was reported for **26** (i.e., K_i of 17.3 nM for hCA II). As for the heterocyclic derivative **28**, predominant inhibition of the housekeeping hCA II was observed (K_i of 8.3 nM), followed by the tumor-associated hCAs IX and XII, which showed K_i values of 28.3 and 47.2 nM, respectively (Table 1).

Among the amide-containing compounds **35a–c**, preferential selectivity for the hCA XII isoform was reported for compounds **35a** and **35c**, with K_i values of 8.2 and 7.5 nM, respectively, whereas the benzyl intermediate **35b** was a medium nanomolar inhibitor (i.e., K_i 64.4 nM). A similar kinetic trend was reported for the hCA IX isoform, although the associated K_i values were in the medium to high nanomolar range (Table 1). Derivative **35b** was poorly effective on hCAs I and II too, with K_i s of 4767 and 620.0 nM, respectively. As for the shortest **35a**, a 26.5 nM inhibition value was reported for hCA II, whereas it was poorly effective on the hCA I isoform (i.e., K_i of 352.5 nM). Finally, the longest **35c** was a high nanomolar hCA I inhibitor with a K_i value of 5515 nM; it was effective on the hCA II isoform at a 55.7 nM concentration, and thus almost equipotent to the IX isozyme. A diverse kinetic trend on the hCAs considered in this study was obtained for sulfonyl derivatives **36a–c**. As reported in Table 1, the entire series was highly selective and potent toward the hCA XII isoform, with K_i values progressively increased from 5.9 nM for **36a** up to 8.1 nM for **36c** (Table 1). As for hCA IX, a 4.1-fold enhancement in the inhibition potency was obtained when the sulfonyl ester connecting moiety in **36a** was replaced with sulfonamide instead to afford **36b** (i.e., K_i s of 311.5 and 41.9 nM for **36a** and **36b**, respectively), whereas slight elongation of the alkyl tether (i.e., **36c**) did not induce significant effects on kinetics (Table 1). The remaining hCAs I/II were scarcely inhibited from **36a–c**, with K_i values in the high nanomolar range (Table 1). A clearer kinetic trend was obtained for the amido containing **37a–c**. Elongation of the alkyl tether in **37a** of a single carbon unit to afford **37b** led to loss of effectiveness for hCA II (i.e., K_i s of 21.4 and 798.6 nM for **37a** and **37b**, respectively) and significant gain of inhibition potency for the hCAs IX and XII isoforms (Table 1). For instance, **37b** was a 7.05-fold more effective hCA IX inhibitor when compared with its shorter counterpart **37a** (i.e., K_i s of 346.3 and 49.1 nM for **37a** and **37b**, respectively); as for the hCA XII, it showed a potency gain of 6.7-fold (i.e., K_i s of 61.0 and 9.1 nM for **37a** and **37b**, respectively). Regioisomeric effects on kinetics were clearly observed for **37b** and **37c** on all hCAs considered, except for the isoform XII (i.e., K_i s of 9.1 and 9.4 nM for **37b** and **37c**, respectively). Both compounds **38** and **39** retained high selectivity and nanomolar potency for the hCA XII isoform, with K_i values of 9.3 and 6.3 nM, respectively. As for the remaining hCAs isoforms, it is worth noting that **39** was an almost equipotent inhibitor of the hCA II and IX isoforms, with K_i values of 77.1 and 76.0 nM, respectively. Heterogenic SAR was reported for the piperazine-containing derivatives **48a–d** and depending upon the introduction of various moieties at the CAI arylsulfonamide warhead. For instance, the unsubstituted derivative **48a** was a selective and potent inhibitor for the hCA XII isoform, with a K_i value of 3.7 nM. A progressive decrease in the inhibition values was obtained for **48a** on hCAs I, II, and IX, respectively (i.e., K_i s of 82.1, 49.1, and 30.6 nM for hCAs I, II, and IX, respectively). Introduction of the chloro atom at the

3-position of the phenyl moiety, as in **48b**, led to a significant reduction of the ligand affinity for the hCA I, IX, and XII isoforms between 1.6- and 9.1-fold (i.e., K_i s of 769.7, 48.4, and 31.1 nM for hCAs I, IX, and XII, respectively). Compound **48b** was beneficial only for isozyme II, as a 2.4-fold inhibition enhancement was obtained (i.e., K_i s of 49.1 and 20.7 nM for **48a** and **48b**, respectively). Substitution of the chloro atom in **48b** with the bulky $-CF_3$ moiety afforded the high potent and selective hCA XII inhibitor **48c** (i.e., K_i of 9.4 nM). Conversely, the fluoro derivative **48d** showed a remarkable increase in the K_i values and loss of selectivity toward all of the isoforms tested (Table 1). As for the 1,4-disubstituted diazepane derivatives **49a–d**, progressive enhancement of the inhibition potency was reported for the unsubstituted **49a** on hCAs I, II, IX, and XII, with K_i values of 315.1, 288.5, 13.8, and 5.5 nM, respectively. Introduction of the chloro atom at the 3-position (i.e., **49b**) led to a reduction of the K_i values for hCAs I and II isoforms, whereas the opposite trend was observed for the IX and XII isozymes, although all the values were in the medium-high nanomolar range (Table 1). Change of the chloro in **49b** with a fluoro instead to afford **49c** further enhanced the inhibition potency for hCAs I, II, and XII up to low nanomolar K_i values (i.e., K_i s of 5.3, 7.2, and 7.9 nM for hCAs I, II, and XII, respectively), whereas a slight increase in the K_i value was reported for the hCA IX isoform (i.e., K_i of 284.6 nM). Fluoro disubstitution, as in **49d**, led to a decrease in the affinity of the ligand toward all hCAs considered in this study (Table 1).

Overall, the compounds synthesized in this study showed interesting in vitro activity toward the *Malassezia* spp. CAs, with K_i values in the low-/sub-micromolar ranges. Specifically, Mpa- and MreCA were preferentially inhibited in terms of their hydase activity over the MgCA isoform.

2.3 | Antifungal Assays on *Malassezia* spp

All synthesized compounds were tested in vitro using the microdilution assay to evaluate the minimum inhibitory concentration (MIC) on *M. pachydermatis* DSM 6172, *M. furfur* ATCC 14521, and *M. globosa* ATCC MYA 4612 reference strains. The data obtained are reported in Table 2 and were compared with the reference drug KTZ.

As reported above, relevant data were obtained for the *M. pachydermatis* DSMZ 6172 strain, as the majority of compounds screened were highly effective growth inhibitors on this yeast, with associated MIC values below the 1.0 μ g/mL threshold value (Table 2). Compound **9a** was the least potent among the entire series (i.e., MIC of 3.6 ± 3.25 μ g/mL), and an almost identical trend was observed for **9b–d**, **24a–d**, and **35b**, as their MICs were between 0.5/0.6 μ g/mL (Table 2). Better results were obtained for compounds **10a** (i.e., MIC 0.33 ± 0.14 μ g/mL), **48a** (i.e., MIC 0.25 ± 0 μ g/mL), and **39** (i.e., MIC 0.125 ± 0 μ g/mL). It is noteworthy that the benzoxazolyl derivative **28** and the shortest amido **35a** were the most effective compounds in inhibiting *M. pachydermatis*, being far more effective than the reference KTZ (i.e., MICs of 0.0078 ± 0 , 0.005 ± 0.002 , and 0.0312 ± 0 μ g/mL, respectively). Derivative **38** was also of interest, with a MIC value of 0.013 ± 0.004 μ g/mL. All the remaining derivatives showed

TABLE 2 | In vitro evaluation of the compounds using the minimum inhibitory concentration (MIC) assay on *Malassezia* spp. (i.e., *M. pachydermatis* DSMZ 6172, *M. furfur* ATCC 14521, and *M. globosa* ATCC MYA 4612). The drug ketoconazole (KTZ) was used as the reference. MIC values were expressed as average MIC ($\mu\text{g/mL}$) of three experiments, with three replicates each $\pm$ standard deviation (SD).

	MIC ($\mu\text{g/mL} \pm \text{SD}$) <i>M. pachydermatis</i> DSMZ 6172	MIC ($\mu\text{g/mL} \pm \text{SD}$) <i>M. furfur</i> ATCC 14521	MIC ($\mu\text{g/mL} \pm \text{SD}$) <i>M. globosa</i> ATCC MYA 4612

comparable potencies, with associated MIC values being between 0.0625 and 0.031 $\mu\text{g/mL}$ and therefore in the same range of the reference KTZ (Table 2).

Far higher MIC concentrations were obtained when the compounds were tested on the *M. furfur* ATCC 14521 strain, as most of the values were between 1 and 4 $\mu\text{g/mL}$, and **10a** was the only ineffective derivative (i.e., MIC of 256 $\mu\text{g/mL}$). Slightly lower effectiveness was reported for derivatives **9a**, **9d**, **24c**, **25**, **26**, **48a**, **48d**, and **49a**, with MICs spanning

between 5 and 16 $\mu\text{g/mL}$ (Table 2). Among the compounds tested, **36a** and **38** were equipotent to the reference KTZ (Table 2), whereas **28** was 2.6-fold less effective (i.e., MICs of 0.67 $\mu\text{g/mL}$). Derivative **23** was the most effective in the series, being 2.0-fold more potent than KTZ (i.e., MICs of 0.125 ± 0 and 0.25 ± 0 $\mu\text{g/mL}$, respectively).

A clearer MIC trend was obtained for the *M. globosa* ATCC MYA 4612 strain. For instance, derivatives **7**, **10a**, **25**, **26**, **28**, **35b**, **36a**, **48a**, **49c**, and **49d** were ineffective, with MIC

values $> 256 \pm 0 \mu\text{g/mL}$ (Table 2). Compounds **35a**, **35c**, and **39** were the first to show MIC effectiveness at a $128 \pm 0 \mu\text{g/mL}$ concentration, followed by **48d**, **36b**, and **10a**, which showed a marked decrease to values of 106.7 ± 36.9 , 64.0 ± 0 , and $26.7 \pm 9.24 \mu\text{g/mL}$, respectively. Compounds **36c**, **38**, and **49a** were almost all equipotent growth inhibitors (i.e., MICs of 16.0 ± 0 and $13.3 \pm 4.62 \mu\text{g/mL}$), followed by derivative **23** (i.e., MIC $10.7 \pm 4.6 \mu\text{g/mL}$). An interesting profile was observed for the remaining compounds. For instance, **48b** was effective at $8.0 \pm 0 \mu\text{g/mL}$, whereas for **48c**, the effective concentration reduced to $5.3 \pm 2.3 \mu\text{g/mL}$. Compounds **37a–c** and **49b** were all equipotent, with MICs ranging between 3.3 ± 1.15 and $4.3 \pm 3.5 \mu\text{g/mL}$. Particularly relevant were the data obtained from **9a–d** and **24a–d**, which were all between 0.5 and $3.0 \mu\text{g/mL}$. Compound **9a** was the most effective growth inhibitor on *M. globosa* among the entire series, with a value of $0.5 \pm 0 \mu\text{g/mL}$ (Table 2). Overall, the compounds obtained in this study were less effective as *M. globosa* ATCC MYA 4612 growth inhibitors when compared with the reference drug KTZ, which showed a MIC value of $0.25 \pm 0 \mu\text{g/mL}$, thus being 13.2-fold more potent than the best-performing compound **37b** (i.e., MIC $3.3 \pm 1.15 \mu\text{g/mL}$).

The most effective compounds were assessed for their effects on human (h) keratinocytes HaCaT cells, considering the values reported by the reference drug KTZ (Figure 2).

Overall, the cell viability of human cells was high in the presence of KTZ derivatives, and among them, the most tolerated compound was **48c**. Derivative **25** was associated with cell survival values that were consistently above the threshold limit. Higher percentages of cell survival were reported for the compounds screened at the highest concentration; in some cases, an increase in the cell population was observed when compared with the negative control with 1% DMSO. This aspect needs to be investigated in depth to assess whether the data obtained by the MTT test can be traced back to an increased cell proliferation that could be quantified through a cell counting kit (CCK-8) [20].

Data in Figure 3 show cell survival percentages closely matching those of KTZ when the compounds were tested at $0.5 \mu\text{g/mL}$, whereas an increase in the concentration up to $16.0 \mu\text{g/mL}$ (i.e., 32-fold higher than the effective dose against *M. pachydermatis*) led to an increase in the viability, with no marked differences for the reference KTZ. Relevant differences were observed at a $256.0 \mu\text{g/mL}$ concentration (i.e., 512-fold higher than the MIC value), as the KTZ induced significantly low keratinocyte survival (i.e., $10.50\% \pm 0.36$), whereas all tested compounds showed just a slight decrease, with percentages ranging from 60% to 90%. On the basis of the data analysis reported above, it is possible to state that although compounds are found to be less effective than KTZ in some cases, they are clearly highly compatible with human cells at high dosages and this endows them with high therapeutic indexes.

2.4 | Sterol Analysis

Based on previous experiments, **9a–d**, **35a**, **38**, **49b**, and **49c** were selected to assess the ability to inhibit the *Malassezia* spp.

CYP51 expressed enzyme by evaluating any disruption in the biosynthesis of ergosterol. Despite our efforts, it proved difficult to grow *Malassezia* spp. (i.e., *M. globosa* and *M. pachydermatis*), and therefore, we performed our experiments on *Candida albicans* instead by administering **9a–d**, **35a**, **38**, **49b**, **49c**, and the reference drug KTZ at the final concentrations listed in Table 3, in agreement with experimentally determined KTZ MIC values [21] and MICs for *M. globosa*.

Each culture was shaken at 30°C for 48 h, followed by sterol extraction and GC-MS identification by comparison of the main peaks (i.e., $> 1\%$ of the dominant peak) with the NIST database spectra available online (Figure 4, Supporting Information S2: Table S1) [22]. Percentage sterolic profiles (% of the total sterol extracted) were determined by calculating the peak areas determined from each identified peak in relation to the total areas of all identified peaks (Supporting Information S2: Table S2).

Overall, the GC-MS traces showed profiles with significant accumulation of 14α -methylated sterol derivatives in *C. albicans* wild-type strains treated with selected compounds and thus confirmed that the KTZ moiety merged within the synthesized molecules retained its mechanism of action. Interestingly, GC-MS traces and sterolic percentages for *C. albicans* treated with **9a–d** and **35a** were almost equal, with derivative **9b** being slightly more effective than the others (i.e., up to 1.6-fold) in determining the accumulation of lanosterol (i.e., 16.6%). Better performances were obtained for **35a**, which, in addition to lanosterol (16.0%), induced significant accumulation of the 14α -methylated derivative 4,4-dimethylcholesta-8, 24-dien-3-ol (i.e., 10.8%), and was associated with the lowest ergosterol content among all (73.2%). Compounds **49b** and **49c** were identical in determining sterolic profiles and contents and were not too dissimilar to the GC-MS trace for **9b** (Figure 3). Derivative **38** was particularly effective in inhibiting the CYP51 enzyme in *C. albicans*, as ergosterol accounted for just 21.5% of the total sterol content, and it induced significant accumulation of 4,4-dimethylcholesta-8, 24-dien-3-ol (i.e., 5.9%), lanosterol (41.6%), and 4,14-dimethyl-9,19-cycloergost-24(28)-en-3-ol acetate (28.8%). It is necessary to point out that the results reported here and based on the *C. albicans* model should be considered as a general reference method that takes into account additional discrepancies among the strains, such as the metabolism of sterol.

3 | Conclusions

Herein, we report the design and synthesis of compounds with the antifungal KTZ pharmacophoric moiety connected by means of alkyl/aryl spacers to a warhead-directed CAI of the primary sulfonamide type. The main aim of this study is to present experimental evidence for next-generation antifungal agents able to inhibit both yeast-expressed 14α -demethylase (CYP51) and CA enzymes.

The library of compounds reported herein was developed using a rational approach based on elongation of the KTZ piperazine

FIGURE 2 | Viability assays on human keratinocytes HaCaT cells expressed as % of cell survival. NC, negative control ($Y = 77\%$) and TR, threshold of survival ($Y = 65\%$).

distal nitrogen conveniently modified with the moieties of interest. No major difficulties were encountered during the synthetic and/or the purification processes up to gram scales, thus proving the sustainability of the approach.

All final compounds showed effective inhibition of the relevant *Malassezia* spp. expressed CAs (i.e., MgCA, MpaCA, and MreCA), with experimental K_i values in the low-sub-micromolar range. Although hCAs were far more susceptible to

inhibition (i.e., K_i s in the low nanomolar range), all compounds had low cytotoxicity, with an overall threshold survival on HaCaT cells of 65% at an 8 µg/mL concentration. MIC values clearly showed that the tested compounds did not have exceptional antifungal efficacy against *Malassezia* spp. strains when compared with KTZ. Nevertheless, a remarkable reduction in cellular toxicity compared with KTZ is quite evident. The low cytotoxic profile of the compounds reported here makes them exploitable at higher concentrations and possibly also for

FIGURE 3 | Viability assays on human keratinocytes HaCaT cells expressed as % survival $\pm$ SD % at three different concentrations (256.0, 16.0, and 0.5 $\mu\text{g/mL}$) and ketoconazole (KTZ) as the reference compound. NC, negative control ($Y = 77\%$) and TR, threshold of survival ($Y = 65\%$).

systemic administration for the management of difficult-to-treat fungal infections as a replacement for KTZ. Such an application would be quite beneficial to eliminate the typical time- and dose-dependent side effects of this molecule (i.e., suppression of testosterone synthesis) [23]. Data reported in this study allow us to reasonably speculate that the compounds tested are inhibitors of the 14α -demethylase enzyme, and suppress ergosterol synthesis along with accumulation of 14α -methylated sterol derivatives within the yeast membranes. The net effect of this process is an additional contribution to reduce the growth of *Malassezia* spp., as observed in our experiments. For clarity, our data are indicative of retention of the KTZ sterol inhibition in reference to *C. albicans*. This model, although scientifically relevant for our purposes, does not consider any differences in the metabolism of cholesterol between fungal strains.

The preferential isoform selectivity of our compounds for the fungal strain-expressed carbonic anhydrases (CAs) over human CAs does not represent a limitation for further development, since *Malassezia* spp. are typically located on superficial cutaneous areas in humans and pets. Overall, we are confident that the compounds reported in this study are effective antifungal agents endowed with high safety profiles, which make them more appropriate for the management of infections promoted by fungal/yeast by means of topical administration.

4 | Experimental

4.1 | Chemistry

4.1.1 | General

Anhydrous solvents and all reagents were purchased from Sigma-Aldrich, Alfa Aesar, and Fluorochem (Milan-Italy). All reactions involving air- or moisture-sensitive compounds were performed under a nitrogen atmosphere using dried glassware and syringe techniques to transfer solutions. Nuclear magnetic resonance ($^1\text{H-NMR}$, $^{13}\text{C-NMR}$) spectra were recorded using a Bruker Advance III 400 MHz spectrometer in $\text{DMSO-}d_6$. Chemical shifts are reported in parts per million (ppm) and the coupling constants (J) are expressed in Hertz (Hz). Splitting patterns are designated as follows: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; dd, doublet of doublets; bs, broad singlet; ap s, apparent singlet; ap d, apparent doublet; ap t, apparent triplet; and ap q, apparent quartet. The assignment of exchangeable protons (OH and NH) was confirmed by the addition of D_2O . Analytical thin-layer chromatography (TLC) was carried out on Merck silica gel F-254 plates. Flash chromatography purifications were performed on Merck silica gel 60 (230–400 mesh ASTM) as the stationary phase, and methanol/dichloromethane (MeOH/DCM) or ethyl acetate/hexane (EtOAc/Hex) were used as eluents. The solvents used in Mass Spectra (MS) measurements were acetone, acetonitrile (Chromasolv grade), and 56 mQ H_2O 18 M Ω , obtained from Millipore's Simplicity system (Milan-Italy). The mass spectra were obtained using a Varian 1200 L triple quadrupole system (Palo Alto, USA) equipped by the Electrospray Source (ESI) operating in both positive and negative modes. Stock solutions of analytes were prepared in acetone at 1.0 mg/mL and stored at 4°C . Working solutions of each analyte were freshly prepared by diluting stock solutions in a mixture of mQ H_2O /ACN 1/1 (v/v) up to a concentration of 1.0 $\mu\text{g/mL}$. The mass spectra of each analyte were acquired by introducing, via a syringe pump at 10 L/min, the working solution. RawQdata were collected and processed by Varian Workstation Vers. 6.8.

The InChI codes of the investigated compounds, together with some biological activity data, are provided as the Supporting Information.

FIGURE 4 | GC-MS traces of the sterol content for each *Candida albicans* culture treated with **9a-d**, **35a**, **38**, **49b**, **49c**, and KTZ as the reference drug.

4.1.2 | Synthesis of 1-(4-[(2*R*,4*S*)-2-[(1*H*-Imidazol-1-yl)methyl]-2-(2,4-Dichlorophenyl)-1,3-Dioxolan-4-yl]methoxy}phenyl)piperazine (2)

In a round-bottom flask, KTZ **1** (2.0 g; 3.78 mmol; 1.0 eq.) was suspended in MeOH (25 mL). The reaction mixture was stirred at reflux temperature until complete dissolution. Then, aqueous NaOH 20% w/v (5–6 mL) was added. The reaction mixture was stirred at reflux temperature for 12 h. A control via TLC was performed to ensure complete consumption of the starting materials. The reaction was cooled to room temperature, diluted with H₂O, and a white precipitate was formed, filtered off under vacuum, washed with H₂O, and dried in air. No further purification was needed. White solid 91% yield; ¹H NMR (DMSO-*d*₆, 400 MHz): 7.73 (1H, d, *J* = 2.08 Hz), 7.60 (1H, d, *J* = 8.44 Hz), 7.51 (1H, s), 7.49 (1H, dd, *J* = 8.54 Hz; *J* = 2.15 Hz), 7.05 (1H, s), 6.89 (2H, d, *J* = 9.12 Hz), 6.85 (1H, s), 6.81 (2H, d, *J* = 9.12 Hz), 4.56 (2H, q, *J* = 11.25 Hz), 4.37 (1H, m, NH exchange with D₂O), 3.90 (1H, t, *J* = 5.01 Hz), 3.67 (2H, m), 3.54 (1H, dd, *J* = 10.20 Hz; *J* = 5.09 Hz), 2.95 (4H, t, *J* = 4.80 Hz), 2.85 (4H, t, *J* = 4.78 Hz), 2.21 (1H, s); ¹³C NMR (CDCl₃, 100 MHz): 152.3, 146.8, 138.8, 135.9, 134.7, 133.0, 131.3, 129.5, 128.6, 127.2, 121.1, 118.1, 115.3, 108.0, 74.9, 67.8, 67.6, 51.8, 51.3, 46.3; ESI-HRMS (*m/z*) calculated for [M+H]⁺ ion species C₂₄H₂₆Cl₂N₄O₃ 488.1382, found 488.1386; Elemental analysis, calculated: C, 58.90; H, 5.36; N, 11.45; found: C, 58.92; H, 5.39; N, 11.43.

4.1.3 | General Procedure for the Synthesis of Ureido Derivatives 7, 9a–d, and 10a,b

1-(4-[(2*R*,4*S*)-2-[(1*H*-Imidazol-1-yl)methyl]-2-(2,4-dichlorophenyl)-1,3-dioxolan-4-yl]methoxy}phenyl)piperazine (**2**) (1.0 eq.) and the appropriate carbamate (**3–6**) (1.0 eq.) were dissolved in acetonitrile (4 mL). The reaction mixture was stirred at reflux temperature for 12 h. A control via TLC was performed to ensure complete consumption of the starting materials. The reaction was quenched with H₂O and the precipitate was filtered off under vacuum, washed with Et₂O and H₂O, and then dried in air. Purification via silica gel flash chromatography was performed to afford the pure products.

4.1.6 | General Procedure for the Synthesis of Compounds 37b,c, 48a–d, and 49a–d

1-(4-(((2*R*,4*S*)-2-((1*H*-Imidazol-1-yl)methyl)-2-(2,4-dichlorophenyl)-1,3-dioxolan-4-yl)methoxy)phenyl)piperazine (**2**) (1.0 eq.) and the appropriate acryloyl derivative (**43–45**) (1.0 eq.) were dissolved in methanol (4–5 mL). The reaction mixture was stirred at reflux temperature for 12 h. A control via TLC was performed to ensure complete consumption of the starting materials. The reaction was quenched with H₂O, and the precipitate was filtered off under vacuum, washed with Et₂O and H₂O, and then dried. Purification via silica gel flash chromatography was performed to afford the pure products.

N-(4-Sulfamoylphenyl)-3-[4-(4-(((2*R*,4*S*)-2-((1*H*-imidazol-1-yl)methyl)-2-(2,4-dichlorophenyl)-1,3-dioxolan-4-yl)methoxy)phenyl)piperazin-1-yl]propanamide (**37b**): Yield 42%. Experimental as reported above.

N-(3-Sulfamoylphenyl)-3-[4-(4-(((2*R*,4*S*)-2-((1*H*-imidazol-1-yl)methyl)-2-(2,4-dichlorophenyl)-1,3-dioxolan-4-yl)methoxy)phenyl)piperazin-1-yl]propanamide (**37c**): Yield 48%. Experimental as reported above.

4.2 | In Vitro CA Inhibition Assay

The CA-catalyzed CO_2 hydration activity measurement was performed on an Applied Photophysics stopped-flow instrument using phenol red, at a concentration of 0.2 mM, with a pH indicator with 20 mM HEPES (pH 7.5) as the buffer, 20 mM Na_2SO_4 , and following the initial rates of the CA-catalyzed CO_2 hydration reaction for a period of 10–100 s and working at a maximum absorbance of 557 nm. The CO_2 concentrations ranged from 1.7 to 17 mM. Enzyme concentrations varied between 5 and 12 nM [24, 25]. For each inhibitor, six traces of the initial 5%–10% of the reaction have been used to determine the initial velocity. The uncatalyzed reaction rates were determined in the same manner and subtracted from the total observed rates. Stock solutions of inhibitors (0.1 mM) were prepared in distilled H_2O , and dilutions up to 0.01 nM were prepared. Solutions containing an inhibitor and an enzyme were preincubated for 15 min at room temperature before the assay to allow the formation of the E–I complex. The inhibition constants were obtained by nonlinear least-squares methods using PRISM 3 and the Cheng–Prusoff equation as reported earlier [26], and represent the mean from at least three different determinations. All CAs were recombinant ones and were obtained in-house [27, 28].

4.3 | Antifungal Activity Evaluation Methods

All the fungal strains were stored at -80°C in cryovials, and then the inoculum preparations for broth microdilution antifungal assays were performed following the CLSI guidelines for antifungal susceptibility testing of yeasts, with some minor modifications (Clinical and Laboratory Standards Institute (CLSI) [29]. Briefly, yeasts *M. pachydermatis* DSMZ 6172 (CDC 16334) (MP), *M. furfur* ATCC 14521 (MF), and *M. globosa* ATCC MYA 4612 (MG) were inoculated into 6 mL of modified RPMI 1640 broth (Gibco, Life Technologies Limited, UK) with the addition of ingredients suggested by Rojas et al. and incubated at 37°C for 48 h for MP and MF, while MG was incubated at 35°C for 72 h [30]. The fungal inoculum was prepared by suspending in phosphate buffer (PB), 10 mM pH 7 four to five colonies of about 1 mm diameter. The fungal suspension was then adjusted to an optical density of 0.5 McFarland, to reach a final concentration in the wells of the plates of 5×10^5 CFU/mL. Tested compounds

were dissolved in DMSO at 25.6 mg/mL, and then two-fold dilutions of the tested compounds were performed to reach final concentrations ranging from 256 to $0.00390 \mu\text{g/mL}$. KTZ (purchased from Sigma Aldrich, Saint Louis, MO USA) was dissolved in DMSO at a concentration of 25.6 mg/mL and tested at a final range of 32– $0.008 \mu\text{g/mL}$. Growth and sterility controls were performed. After 48 h of incubation at 37°C for MP and MF and at 35°C for 72 h for MG, a MIC reading was performed. Quality control strains (*C. albicans* ATCC 11006, American Type Culture Collection, Manassas, VA, USA, and *M. pachydermatis* DSM 6172, German Collection of Microorganisms and Cell Cultures GmbH, DSMZ, Braunschweig, DE) were added each day to check the accuracy of the drug dilutions and the reproducibility of the results. For each test, three experiments were performed, with three replicates each. The MIC value of each tested compound against each strain was calculated as the average value of replicates ($\mu\text{g/mL}$) $\pm$ standard deviation (SD).

4.4 | Cell Viability Test

Compounds' viability was evaluated on Human Keratinocyte cell line (HaCat) cells (BS CL 168), purchased from Biobanking of Veterinary Resources of Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna (Via Bianchi 9, 25124, Brescia, Italy). In a microtiter 96-well plate, about 5×10^3 cells/mL per well were incubated for 12 h at 37°C in DMEM medium in a humidified atmosphere with 5% CO_2 in the presence of 0.0625 – $8 \mu\text{g/mL}$ of the tested compounds and KTZ. Negative controls were performed both with 1% DMSO and with cells and DMEM only. After incubation, $10 \mu\text{L}$ of MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) (Sigma Aldrich, Saint Louis, MO, USA) was added to each well and incubated at 37°C for 6 h. At the end of the incubation, $100 \mu\text{L}$ of the solubilization solution (10% SDS in 0.01 M HCl) was added to each well and then incubated for 12 h. The yellow tetrazolium MTT salt is reduced in metabolically active cells to form insoluble purple formazan crystals, which are solubilized by the addition of a detergent. After incubation, plates were read using a spectrophotometer, and the optical density was measured at 540 nm [31].

4.5 | Sterol Analysis

4.5.1 | Compound Dilution

A volume of 1.0 mL of dimethyl sulfoxide (DMSO) was added to **9a–d**, **35a**, **38**, **49b**, **49c**, and the reference drug KTZ, which were serially diluted to 1, 100, and $10 \mu\text{g/mL}$ in Modified Dixon (DM) media and stored at -20°C . A volume of 1.0 L DM adjusted to pH 6 contained 36 g of malt extract, 20 g of desiccated Ox-Bile, 6 g of peptone, 10 mL of Tween 40, 2 mL of glycerol, and 2 mL of oleic acid.

4.5.2 | Culturing of Wild-Type *C. albicans*

C. albicans was cultured in 10 mL of YPD media in 60 mL pots at 30°C for 2 days. A volume of 1.0 L of YPD for agar plates contains 2% agar, 10 g of yeast extract, 20 g of peptone, and 20 g of glucose.

4.5.3 | Drug-Treated Growth of *C. albicans*

Final concentrations of **9a-d**, **35a**, **38**, **49b**, **49c**, and the reference drug KTZ were based on the MIC value for KTZ from previous work [21] and the MIC values for *M. globosa* reported in Table 2. The media were spiked with each drug to obtain the final concentrations and inoculated with 100 μ L of culture to obtain 10 mL of culture. The cultures were incubated at 30°C with shaking for 2 days.

4.5.4 | Cells Pelleting From *C. albicans*

A total of 1.0 mL from each culture was transferred to 1.5 mL eppendorph tubes and centrifuged at 3000 rpm for 3 min. The supernatant was removed, and another 1 mL of culture was added and centrifuged at 3000 rpm. This procedure was repeated so that in total, 3 mL of culture was pelleted. The supernatant was removed, and the pellet was resuspended in deionized H₂O, centrifuged at 3000 rpm for 3 min. This was repeated once more. The supernatant was removed, and the pellet was stored at −20°C until sterols were extracted.

4.5.5 | Sterol Extraction

Each pellet was resuspended in 1.0 mL of MeOH and transferred to glass test tubes. A volume of 3 mL of 60% w/v KOH and MeOH (1/1) was added. A volume of 1.0 mL of 0.5% pyrogallol was added; glass marbles were placed on top of the test tubes and covered with an aluminum foil. The sample was vortexed for 30 s to mix the components, heated in a water bath at 80°C for 2 h, and allowed to cool. Approximately 1.0 mL of *n*-hexane was added to each tube, which was then vortexed for 30 s, and allowed to settle to form two layers. The top *n*-hexane layer containing the sterols was removed and transferred to a 2 mL glass vial. This was repeated so that approximately 2 mL of the *n*-hexane fraction was collected. *n*-hexane was dried under a flow of nitrogen, leaving a dried residue of sterols, which was derivatized by adding 400 μ L of pyridine and 100 μ L of BSTFA, and heating at 70°C on a hot block for 1 h.

4.5.6 | GC-MS Sterol Analysis

Trimethylsilyl (TMS)-derivatized sterols were analyzed using a Thermo Trace 1300 GC system (Agilent Technologies) coupled to a Thermo ISQ LT-MS unit and identified with reference to retention times and fragmentation spectra for known standards. A DB-5MS fused silica column (30 m $\times$ 0.25 mm $\times$ 0.25 μ m film thickness) was used for all GC separations (J&W Scientific). The initial oven temperature was held at 70°C for 4 min, followed by ramping (25°C/min) to a final temperature of 280°C; this temperature was held for 25 min. Samples were analyzed in splitless mode (1 L injection volume) using helium carrier gas and electron impact ionization (ion source temperature, 290°C) and scanning from 50 to 700 atomic mass units (amu). GC-MS data files were analyzed using Agilent software (MSD Enhanced ChemStation) to generate sterol profiles and for the derivation of integrated peak areas.

Acknowledgments

F.C. was grateful to Ente Cassa di Risparmio di Firenze for partially supporting this work. Project title “Progettazione e Sintesi di Nuovi Agenti per la Cura e la Profilassi di Infezioni Batteriche Resistenti”. CRF 2018.1001.
