Abstract

Background: It is widely accepted that rehabilitation combined with pharmacological approach could improve pain, spinal mobility and functional status in ankylosing spondylitis (AS). Feldenkrais-Core Integration (FCI) method is a mind body therapy based on low impact exercises focusing on better body organization, postural re-education and balance improvement.

Aims: Our aim was to assess in a pilot study the utility and feasibility of FCI approach in the treatment of AS.

Setting: Outpatient Clinic of the Division of Rheumatology, Department of Experimental and Clinical Medicine, University of Florence.

Methods: Ten AS patients were recruited to perform a FCI physiotherapeutic program of 10 supervised group sessions (60 min, twice a week). Clinic and clinimetric measurements including pain, fatigue, global health status (VAS), disease effect on wellbeing (BAS-G), functional status (BASFI, HAQ-S), disease activity (BASDAI), enthesitis (MASES) and anthropometric measurements of lumbar mobility and cervical mobility were assessed at baseline (t=0) and at the end of the study (t=1). At t=1 patients' satisfaction, attendance rate and attrition rate were assessed. Only descriptive statistics was performed.

Results: Our results showed improvements in pain, fatigue, global health status, BAS-G, BASFI, HAQ-S, MASES, BASDAI, lumbar lateral flexion and cervical range of motion (cervical forward flexion, extension, lateral flexion and rotation) at the end of the study compared to the baseline. Greater improvements in percentage are found in pain, fatigue, self perceived health status, functionality and tenderness on enthesial sites. No dropouts were registered.

Introduction

Ankylosing spondylitis (AS) is a chronic, progressive, immunoinflammatory disease that predominantly affects the sacroiliac joints and the whole spine [1]. AS may be associated with extra-spinal manifestations, such as peripheral arthritis, uveitis, and cardiovascular complications with functional impairment [2], disability and poor quality of life [3]. The estimated prevalence in European-Caucasian population ranges from 0.1 to 1.4 [1], in Italy is about 0.37% [4]. AS is mainly characterized by chronic

inflammatory sacroiliac pain, spinal stiffness, loss of motility of the spine and serious postural abnormalities.

Postural changes associated with AS include loss of lumbar lordosis, accentuation of the thoracic kyphosis, inversion of cervical lordosis and hip flexion [5]. Such condition may affect the global functional status and social wellbeing restricting interpersonal communication and basic activities of daily living [6]. Moreover, fixed thoracolumbar hyperkyphosis induces the

forward and downward shift of the body's centre of mass with respect to the base of support. Consequently in AS patients the extension of the hips, flexion of the knees and plantar flexion of the ankles occur to maintain balance [7].

AS subjects may have balance alterations associated with poor posture, joint deformities, muscle atrophy and pain [8]. The reduction of the range of movement of the head and neck may worsen balance problems hampering gaze stability [9].

The primary goal in the treatment of AS patients is to reduce pain and inflammation, to prevent permanent structural damages, and to maintain the highest possible functional status and health related quality of life.

ASAS/EULAR recommendations for the management of ankylosing spondylitis state that the optimal management of AS requires a combination of pharmacological and non-pharmacological treatments. TNF blocker agents have been shown to improve significantly spinal pain, function and peripheral joint arthritis in the short term and in the long term follow up in patients with persistently high disease activity despite conventional therapies [10]. Non pharmacological treatment include patient education and exercise both individually and in groups [11]. Patient education and behavioral therapy seem to improve anxiety and motivation, but there are no evidences of their effectiveness on disease's symptoms and disability. Individual and group exercises play an important role in all stages of the disease owing to associated improvements in function and pain. Global assessment is better in AS patients involved in physiotherapeutic group treatments [12]. Although benefits of combination treatment including rehabilitation and TNF inhibitors are well described in literature [13,14] current evidence shows that a specific exercise protocol has not been validated yet [12].

Feldenkrais-Core Integration (FCI) method developed by Josef Della Grotte [15] derives from Feldenkrais® method principles [16] and integrates them with the myofascial chain concepts [17]. The concept of myofascial chain originates from the assumption that the muscles of the human body do not function as independent units. Instead, they are regarded as part of a tensegrity-like, body-wide network, with fascial structures acting as linking components [18].

Feldenkrais® method is a movement pedagogy designed to improve function in activities of daily living, work and recreation through an increasing awareness about movement habits, as well as to find alternative ways of using the body [19]. Feldenkrais® method aims to help people become self-directed learners through specific use of sensimotor experiences and exploratory processes of moving [20].

FCI approach emphasizes the importance of postural re-education, balance improvement and promotes active involvement of the patient in the rehabilitation program. It provides for a global approach in order to take care of the overall

health of a patient, treating not only the districts affected, but the whole musculoskeletal system. FCI offers a new mapping system to re-organize movements and to remove incorrect motor patterns.

Although clinical studies focused on the efficacy of FCI in AS patients are still lacking, many authors show beneficial effects of Feldenkrais® method in improving balance [21] and mobility [22] and in reducing pain (VAS - Visual Analogue Scale) [23] and disability (WDI- Waddell Disability Index) [24] in patients with chronic low back pain [25]. A tailored FCI intervention in posturopatic patients improved significantly the global postural score and had positive effects both on tonic postural state and dynamic postural parameters [26]. The sum of twenty-five postural parameters, assessed applying the ISTAP (The Institute of Postural Analysis, Florence, Italy) diagnostic protocol, affords the global postural score. Postural parameters were evaluated with a specific kinematic examination in addition to the assessment of static and dynamic forces while walking [27].

Based on these results, we hypothesized that FCI may have positive effects on signs and symptoms of spondyloarthritis. Therefore in this pilot study the main aim was to evaluate the utility of FCI method in the treatment of AS patients, focusing on pain, fatigue, global health status, disability, spinal range of motion and disease activity.

Materials and Methods

Subjects

Ten AS patients, 5 men and 5 women, were recruited, consecutively from January 2016 to June 2016, from the outpatient clinic of the Division of Rheumatology, Department of Experimental and Clinical Medicine, University of Florence. Inclusion criterion was the diagnosis of ankylosing spondylitis according to modified New York criteria [6]. Patients recruited signed a written informed consent for all the procedures in accordance with Helsinki Declaration of 1975/83. The study was approved by local Ethical Committee.

All patients continued their pharmacological treatments and throughout the period of the study they were asked not to start any new pharmacological and non pharmacological therapy.

Rehabilitation

AS patients were included in a FCI physiotherapeutic program of 10 sessions (maximum 5-6 participants) each lasting about 60 minutes, twice a week. The lessons were conducted by a physiotherapist (LM) who is experienced and trained in FCI method. The physiotherapeutic protocol included home exercises chosen by the therapist and tailored on the patient, performed daily (30minutes/day) during the whole treatment period.

Feldenkrais-Core integration method

FCI intervention has at least three functional and structural outcomes:

- A. Better body organization and postural equilibrium;
- B. Greater efficiency and energy conservancy;
- C. Greater kinetic energy by gathering potential energy in muscles.

The main assumption of this training is that central nervous system (CNS) can best track and organize efficient movement when there is a recognition of clear direction to, and perceived connection with, functional-structural pathways. The process leads to static and dynamic equilibrium through muscular and myofascial integration. Core integration method has identified and mapped six core movement pathways to describe and account for the transmission of forces in any biomechanical system. The core pathways are a mapping construct of how the body system organizes itself through movement for appropriate functional use.

The pathway used is defined with the following concepts:

- A. It contains a vector of force, direction, and myofascial tensegrity; it passes through the center of gravity and represents the most efficient expenditure of energy
- B. It has specific anatomical features and can be tracked through specific joint angles, actions of levers, muscle chains and fascial tensile spread
- C. It requires lengthening by virtue of mechanical levering and the physiology of myofascial actions
- D. Muscles in the sequential contracting-lengthening phase stimulate tensile fascial spread [15,26].

In each lesson the FCI approach consisted in:

- A. Core integration (CI) group exercises aimed at strengthening deep muscle, improving body flexibility and stability. They consist in an application of a movement map based on six core movement pathways which enables the patient to organize movements with better efficiency and less expenditure of energy.
- B. Feldenkrais®-based Awareness Through Movement group lessons aimed at gaining control of how the body system organizes itself through movement and constructing correct motor patterns. The key is in identifying the paths, assessing movement and posture, tracking how movement is transmitting, and determining through client response whether CNS receives and fixes the image [15,26].
- C. The lessons were sequential, and each lesson dealt with themes from the previous session. FCI kinetic protocol would be interrupted in case of clinical worsening (increased pain, stiffness or fatigue).
- D. The exercise program proposed is further detailed in Table 1.

Table 1: Feldenkrais-Core Integration training program: exercise description and objectives.

First Lesson	
Exercise description	Objectives
Exercises of conscious respiration	To help maintain or improve chest expansion. To help relaxation and concentration on training program.
Feldenkrais®-based Awareness Through Movement group exercises focused on perception of the body while the subject is laying on a mat. These exercises are proposed at the beginning, at the end of the lesson and when the patients are asked to switch body position.	To enhance perception of specific body segments characteristics in terms of dimensions, weight, consistency and symmetry.
Self massage training session with a sensory ball.	To gain patient's perception of specific body segments, particularly of painful areas.
From 2nd to 10th lesson	
Exercise description	Objectives
Exercises of conscious respiration	To help maintain or improve chest expansion. To help relaxation and concentration on training program.
Feldenkrais®-based Awareness Through Movement exercises (see first lesson)	To enhance perception of specific body segments characteristics in terms of dimensions, weight, consistency and symmetry.
CI exercises in different positions (supine, prone, sitting, standing, crawling and lateral decubitus) using elastic bands, lumbar rollers, disc'o'sit inflatable cushions and sensory balls.	To identify the paths, assessing movement and posture, tracking how movement is transmitting. To find alternative ways of using the body. To remove incorrect motor patterns.
Home exercises	
Exercise description	Objectives
Self massage with sensory ball	To improve the patient's recollection of technique and exercise prescription
CI exercises	

Measurements

At baseline (t=0), patients were evaluated for demographic characters (sex, age), disease duration and type of joint involvement. Presence of sacroiliac pain, arthritis, enthesitis, thoracic pain, dactylitis and uveitis was also assessed. Previous physiotherapy treatments and sportive activities were evaluated. All patients were assessed by clinic and clinimetric tools at t=0 and at the end of the study (t=1) for pain, fatigue, global health status, effect of AS on patients' wellbeing, functional status, disability, disease activity and enthesitis. Anthropometric measurements of lumbar and cervical mobility were also documented. At the end of the physiotherapeutic treatment (t=1) patients' satisfaction, attendance rate and attrition rate were assessed.

Clinic and clinimetric measurements

A. Pain was rated with an auto-administered Visual Analogue Scale (VAS 0-10), which measures current pain intensity on a 0-10 scale (0 = no pain, 10 = worst pain [23]).

B. Fatigue was rated with an auto-administered Visual Analogue Scale (VAS 0-10), which measures current fatigue intensity on a 0-10 scale (0 = no fatigue, 10 = worst fatigue).

C. Global health status was rated with an auto-administered Visual Analogue Scale (VAS 0-10), which measures current global health status intensity on a 0-10 scale (0 = worst health status, 10 = best health status).

Disease effect on wellbeing was rated by Italian version of Bath Ankylosing Spondylitis Global Score (BAS-G) which asks patients to indicate the effect of AS on their well-being over the last week and the last 6 months, using a 100 mm horizontal visual analogue scale, where none = 0 and very severe = 100. The mean of the two scales affords the BAS-G score a value between 0 and 100, with a lower score indicating less disease burden [28].

Functional status was rated by Italian version of Bath Ankylosing Spondylitis Functional Index (BASFI) which is composed by ten questions elaborated to determine the degree of functional limitation in patients with AS. Each question is answered using an 11-points numerical rating scale (NRS), with a recall period of the past week. The mean of the ten scales affords the BASFI score a value between 0 and 100, with a lower score indicating less functional limitation [29,30].

Disability was rated by Italian version of Health Assessment Questionnaire-Spondyloarthropathies (HAQ-S) which is a self-report questionnaire referring to global disability, ranges from 0 (no difficulty) to 3 (unable to do) [31].

Disease activity was rated by Italian version of Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) which has six 11-points NRS to measure the severity of fatigue, spinal and peripheral joint pain, localized tenderness, and morning stiffness in patients with AS. Each item is provided using a 0-100 horizontal NRS, to extremes the adjectival descriptors "none" and "very severe". Item six (duration of morning stiffness) is related to a time scale (0-2 h). The mean of items five (severity of morning stiffness) and six is calculated separately. The BASDAI, a number from 0 to 100, is obtained with the mean of this result with the previous four items. Lower scores are indicating lower disease activity. The cut-off of four is used to define the presence of an active disease [32].

Enthesitis was documented by Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) which evaluates the presence or the absence of tenderness in 13 enthesial sites. Tenderness on physical examination is recorded as either present (1) or absent (0) for each of the 13 sites, for an overall score range of 0 -13 [33].

Anthropometric measurements

Lumbar mobility

A. Forward flexion was documented by Schöber test and finger floor distance (FFD).

Schöber test - Two reference points (spinous process of L5 and 10 cm above) were marked on the patients' low back region while they stood in erect position with feet together. Then the patients bent maximally forward and the new distance between the upper and lower marks was measured. Distances of 14.5-15 cm are considered normal [34]. FFD - The patients bent maximally forward trying to touch the floor. The distance between fingers and floor was reported (cm).

B. Lateral flexion - The patients bent laterally to the right and to the left. The distance between fingers and floor was reported for each side (cm).

Cervical mobility

A. Flexion and extension of the head: The patients bent the head maximally forward and backward. The distances between chin and suprasternal notch were reported (cm).

B. Lateral flexion of the head: The patients bent the head laterally to the right and to the left. The distance between tragus and acromion process were reported for each side (cm).

C. Head rotation: The patients rotated maximally the head to the right and to the left. The distance between chin and acromion process were reported for each side (cm).

Patient's feedback

Patient satisfaction with physiotherapeutic treatment was evaluated with a questionnaire measuring seven items (self perceived wellbeing, pain and stiffness reduction, movement fluency and easiness, enjoyableness of the physiotherapeutic program and willingness to continue the treatment) each one rated with an auto-administered Visual Analogue Scale (VAS), reporting the measure on a 0-10 scale (0 =no satisfaction, 10 =best satisfaction). The overall satisfaction, a number from 0 to 70, is obtained summing VAS scores of the previous seven items. Lower scores are indicating lower satisfaction. Attendance rate was reported as total hours of patients' attendance/total hours patients' treatment ratio (%); Attrition rate was reported as Dropouts/Patients recruited ratio (%).

Data analysis

Descriptive statistics for nominal data were expressed in percentages. Continuous variables were described as mean and standard deviation ($M \pm SD$). To assess improving parameters over the period of study differences between means and percentage changes were evaluated (SPSS statistical package, version 20.0 for Windows, SPSS, Chicago, USA).

Results

Table 2: Baseline and demographic characteristics for the patients enrolled.

	Mean±SD	Min-max
Age (years)	55,30±12,05	(32-72)
Disease duration (years)	18,60±18,63	(1-52)
Numbers and Percentages		
Gender (M/F)	5/5 (50%)	
Occupation	7/10 (70%)	
Previous sportive activities	3/10 (30%)	
Previous physiotherapy treatments	6/10 (60%)	

Joint involvement:	
• axial	6/10 (60%)
• peripheral	2/10 (20%)
• axial-peripheral	2/10 (20%)
Sacroiliac pain	8/10 (80%)
Arthritis	4/10 (40%)
Enthesitis	6/10 (60%)
Thoracic pain	3/10 (30%)
Dactylitis	2/10 (20%)
Uveitis	1/10 (10%)

Table 3: Clinic and clinimetric evaluations at baseline (t=0) and at the end of the treatment (t=1). Differences in mean evaluations between t=0 and t=1. Percentage changes between t=0 and t=1.

	Mean (ds) t=0	Mean (ds) t=1	Mean (ds) Delta (t1-t0)	Percentage changes (t1-t0)
VAS Pain	3,80±2,34	3,39±2,38	-0,41±1,20	10,79%
VAS Fatigue	4,37±2,63	3,49±2,10	-0,88±1,60	20,14%
VAS Global health status	4,32±2,60	5,32±2,51	1,00±3,47	23,15%
BAS-G	43,50 ±19,78	36,00 ±27,72	-7,5±20,09	17,24%
BASFI	22,95 ±15,83	19,9±19,2	-3,05±13,78	13,29%
HAQ-S	0,48±0,52	0,44±0,72	-0,47±0,36	8,33%
BASDAI	42,35 ±16,45	40,91 ±19,89	-1,44±13,67	3,40%
MASES	4,33±4,03	3,50±4,09	-0,80±1,62	19,17%
Schöber Test (cm)	2,20±1,51	2±1,70	-0,20 (0,92)	Not improved
Lumbar lateral flexion (right) (cm)	53,10±5,92	52,70±6,40	-0,40±2,27	0,75%
Lumbar lateral flexion (left) (cm)	54,30±6,18	53,60±6,33	-0,70±1,50	1,29%
Lumbar forward flexion (cm)	20,95 ±18,66	22,90 ±16,24	1,95±12,09	Not improved
Cervical forward flexion (cm)	3,85±3,68	3,70±3,71	-0,15±1,70	3,90%
Cervical extension (cm)	17,30±2,11	17,80±2,04	0,50±1,55	2,89%
Cervical lateral flexion (right) (cm)	15±2,54	14,85±1,20	-0,15±2,00	1,00%
Cervical lateral flexion (left) (cm)	14,85±2,60	15,55±1,50	0,70±2,31	Not improved
Cervical rotation (right) (cm)	16,60±4,40	16,20±2,69	-0,40±2,28	2,41%
Cervical rotation (left) (cm)	17±4,16	16,45±2,83	-0,55±2,17	3,24%

Ten AS patients, 5 men and 5 women, were enrolled and assessed. Their baseline characteristics are summarized in Table 2. The differences between the means of the clinical and clinimetric evaluations at t=0 and at t=1 show that FCI physiotherapeutic sessions had positive effects on pain, fatigue, global health status, BAS-G, BASFI, HAQ-S, BASDAI, MASES, lumbar (lateral flexion) and cervical mobility (flexion/extension, lateral flexion and lateral rotation of the head) (Table 3). The adherence to FCI physiotherapeutic program was complete. No dropouts were registered. The attendance rate was 78,6%. The patients' satisfaction score was $58,0 \pm 6,75$.

Discussion

AS is a systemic, chronic rheumatic disease that predominantly affects axial skeleton with severe sacroiliac pain and impaired spinal mobility leading to disability [35] and reduced quality of life [3]. Modifications in spinal posture begin at early stages of the disease and become more marked over the time [36] and account for balance problems [37]. The optimal management of AS requires a combination of tailored pharmacologic and non-pharmacologic interventions aiming at treating inflammation and pain, preventing structural deformities, increasing spinal motion [10,12] and improve overall function and quality of life [38]. Despite the evidences about the effectiveness of physiotherapy in AS, a specific physical exercise protocol has not been established yet [39].

Global Posture Reeducation (GPR) method, a form of active overall muscle stretching working on strengthening and improving flexibility of specific muscle chains offered promising results in restoring spinal mobility (BASMI) and functional capacity (BASFI) in AS patients group sessions managed by a trained physiotherapist [40]. GPR group intervention demonstrated to maintain improved parameters after 6 months and one year follow-up [41]. GPR individual treatment in AS showed significantly greater improvement in morning stiffness duration, spinal mobility parameters (chin to chest distance, occiput to wall distance, cervical rotation, modified Schöber test [42]), chest expansion and self perceived physical wellbeing (SF36 - Short Form 36 Health Survey [43]) than the control group treated with segmental stretching and breathing exercises [44].

Pilates body conditioning method, a well known formula of over 500 physical exercises focusing on stretching and strengthening body core muscles [45] was suggested as a beneficial exercise therapy in patients with musculoskeletal spinal problems increasing proprioceptive balance (Stork stand test) and flexibility (Sit and reach test) [46], reducing disability (OSWDQ - Oswestry Low Back Pain Disability Questionnaire [47]) and pain intensity (VAS) [48,49]. In AS patients Pilates showed positive outcomes on chest expansion, Bath Ankylosing Spondylitis Metrology Index (BASMI) and BASDAI in a short term follow up, and significant improvements of functional status and BASMI after 6 months compared to the baseline [50].

In a recent study involving early AS patients in a specific McKenzie kinetic program aimed at assessing and treating

spinal and postural problems, significant improvements in pain, metrology (BASMI, FFD, chest expansion, modified Schöber test), function (BASFI) and disease activity (BASDAI) were registered compared to the baseline and to the control group [51]. Moreover a specific protocol combining McKenzie, Pilates & Heckscher [52] conducted in a group setting and followed by a maintaining home exercise regimen registered significantly beneficial effects on pain, spinal mobility, BASDAI, BASMI and chest expansion in AS patients [53].

Aquatic exercises have been used for many years in the treatment of musculoskeletal conditions. In this context hydrotherapy effectiveness is widely reported [54]. The benefits of aquatic exercise arise from the physiological effects of immersion and hydrodynamic principles of exercise in the aquatic environment [55-57]. An in-patient rehabilitation program including hydrotherapy, basic exercises for movement, muscle strength and stability, balance and coordination improved disease activity (BASDAI), spinal mobility (BASMI, FFD), chest expansion and gait velocity (6m gait velocity test) in AS patients [58]. A randomized trial exploring three exercise regimens in AS showed beneficial effects of hydrotherapy on pain and stiffness. However any significant improvement was found at 6 months follow up [59].

Feldenkrais Core Integration method is a somatic rehabilitation technique with low physical impact and few side effects. FCI is counted among mind body therapies (MBT) and is focused on gaining perception and body awareness in order to recognize and correct abnormalities such as muscle contractions and posture misalignments and consequently to reduce analgic and non functional posture. Several studies demonstrate that MBT, increasing the abilities of the mind to influence body characteristics and disease symptoms, are effective and useful in the rehabilitation of chronic rheumatic patients, especially in improving function, pain and reducing social and psychological problems [60-63]. Despite their potential utility, few MBT were evaluated in AS.

The present study is the first aimed at assessing the feasibility and the utility of Feldenkrais Core Integration method in the treatment of AS. Our results showed improvements in pain, fatigue, global health status, BASDAI, BAS-G, BASFI, MASES, HAQ-S, lumbar lateral flexion and cervical range of motion (cervical forward flexion, extension, lateral flexion and rotation) at the end of the study compared to the baseline. Greater improvements in percentage are found in pain, fatigue, self perceived health status, functionality and tenderness on enthesial sites. This suggests the utility of FCI in improving flexibility and movement fluency and in re-organizing body schemas trying to eliminate analgic postures. Effects on clinimetric parameters were scanty probably due to the short duration of the physiotherapeutic interventions and the exiguous number of sessions performed. Moreover the wide range of disease duration in our sample may explain the different response to the therapy and may affect the results of the study.

FCI method provides for a global approach and focuses on the close relationships between mental and somatic dimensions [15]. Therefore it allows to reach physical and emotional well-being and to increase the patient's overall health. Our results seemed to confirm these concepts, in fact the greatest improvement in percentage was found in self perceived global health status.

FCI, characterized by low physical impact approach, is always respectful of the pain threshold. These latter guarantees a high adherence to the rehabilitation program and reduces the probability of dropouts. In fact in our study no dropouts were registered and the patients' satisfaction was adequate.

Owing the exploratory nature of the present study, the small sample size and the short term intervention, inferential statistical tests were not performed. Further investigations on wider cohorts of patients and longitudinal design are required to confirm the utility of FCI as an important rehabilitation tool in AS.

Conclusion

Feldenkrais Core Integration method is a movement based MBT with potential effects on muscle contractures, pain and stiffness. Its global approach recognizes the interactions between mind and body in supporting health and allows the patients to achieve physical and psychological wellbeing. The present study showed that FCI approach may be a useful and feasible non-pharmacologic approach in the treatment of patients with ankylosing spondylitis. FCI had positive effects on pain, fatigue, global health status, disease activity, functional status and enthesitis. Our results should be validated by prospective studies with larger sample size.

Conflict of Interest

No financial supports or any other benefit, which could create a potential conflict of interest with regard to the work, are declared.

**Your next submission with JuniperPublishers
will reach you the below assets**

- Quality Editorial service
- Swift Peer Review
- Reprints availability
- E-prints Service
- Manuscript Podcast for convenient understanding
- Global attainment for your research
- Manuscript accessibility in different formats
(Pdf, E-pub, Full Text, audio)
- Unceasing customer service
