ABSTRACT The synthesis of three racemates and the corresponding non-chiral analogues of a C5-methyl pyridazine series is described here, as well as the isolation of pure enantiomers and their absolute configuration assignment. In order to obtain optically active compounds, direct chromatographic methods of separation by HPLC-UV were investigated using four chiral stationary phases (CSPs: Lux Amylose-2, Lux Cellulose-1, Lux Cellulose-2 and Lux Cellulose-3). The best resolution was achieved using amylose tris(5-chloro-2-methylphenylcarbamate) (Lux Amylose-2), and single enantiomers were isolated on a semipreparative scale with high enantiomeric excess, suitable for biological assays. The absolute configuration of optically active compounds was unequivocally established by X-ray crystallographic analysis and comparative chiral HPLC-UV profile. All compounds of the series were tested for formyl peptide receptor (FPR) agonist activity, and four were found to be active, with EC₅₀ values in the micromolar range. KEY WORDS: liquid chromatography; chiral stationary phase; Lux Cellulose; Lux Amylose; absolute configuration; pyridazinones; FPRs; inflammation

INTRODUCTION

Inflammation is the first response of the immune system to infection, irritation, and trauma, and it plays a central role in the pathogenesis of many human diseases, such as asthma, rheumatoid arthritis, multiple sclerosis, cancer, and Alzheimer’s disease.¹ The inflammatory response requires tight regulation and control to avoid overshooting, prolongation, and self-induced damage.² Considering that most currently used anti-inflammatory drugs have important limitations,³ the extensive search to find immunomodulatory agents that regulate innate immune responses represents a promising strategy for treating inflammation and infectious diseases.

The development of bioactive molecules that selectively stimulate the immune system represents an important challenge in medicinal chemistry.⁴ To this end, the modulation of formyl peptide receptors (FPRs), mediators of key events in the regulation of endogenous inflammation and resolution of inflammation, represents a distinctive approach to control inflammatory events.⁵ FPRs belong to the seven transmembrane domain G protein-coupled receptor (GPCR) family, and three subtypes have been identified in humans (FPR1, FPR2/ALX, FPR3) which exhibit a high level of amino acidic homology.⁶ Being expressed in the majority of white blood cells, FPRs interact with a wide range of structurally different pro- and anti-inflammatory ligands associated with different diseases.

Previously, we identified a large number of potent pyrazidine-based FPR1/FPR2 agonists.⁷ Starting from the literature evidence that chiral C4- or C5-substituted pyridazines are generally of particular interest to search for biological activity,⁸–¹⁰ as well as reports that stereoselective interaction may enhance the binding with FPRs,¹¹–¹⁴ we report herein the synthesis of a new series of chiral C5-methyl pyridazine derivatives (compounds (±)-4a-c, Fig. 1) and the corresponding aromatic non-chiral analogues (8a-c) in order to further investigate the role of stereochemistry in their pharmacological activity. Due to the hypothetical stereoselectivity of the drug–receptor interaction, we developed a chiral stationary phases (CSPs)/elucent system suitable for a semi-preparative scale and performed chiral HPLC-UV separation of optically active enantiomers from each racemates (±)-4a-c. Analytical methods on four different CSPs (Lux Amylose-2, Lux Cellulose-1, Lux Cellulose-2, and Lux Cellulose-3) were initially investigated to determine the best resolution conditions, and changes in mobile-phase composition were studied to determine the effect of solvents on the column selectivity. On the basis of the preliminary chromatographic results, the resolution of the racemates was subsequently transferred in the semi-preparative system. The absolute configuration of collected optically active compounds was univocally established by X-ray crystallographic analysis of one of the enantiomers in each pair and by comparative elution order during chiral HPLC-UV analysis. Finally, we investigated the pharmacological properties of all racemates, enantiomers and non-chiral analogues as FPRs agonists using in vitro functional assays.

MATERIAL AND METHODS

Reagents, starting materials, and HPLC-grade solvents were obtained from commercial sources and used without further purification. Extracts were dried over Na$_2$SO$_4$, and the solvents were removed under reduced pressure. All reactions were monitored by thin layer chromatography (TLC) using commercial plates precoated with Merck silica gel 60 F-254.

Semi-preparative HPLC-UV enantioseparations were performed using a Lux Amylose-2, Lux Cellulose-1, Lux Cellulose-2, and Lux Cellulose-3 (50 mm × 4.6 mm I.D., 5 μm particle size; Phenomenex, Bologna, Italy) columns. For analytical enantioseparations, the sample solutions were performed with a Perkin-Elmer 260 elemental analyzer for C, H, N, and the detector wavelength was 254 nm. The signal was acquired and processed by Chemstation revision 1.3.11.1.

General procedure for preparation of racemates (+)-2 and non-chiral analogue 7. A suspension of the appropriate compound (+)-2 or 6 (7.29 mmol) in 6 N NaOH (10 mL) was stirred at 80°C for 3-5 h. The mixture was then diluted with cold water and acidified with 6 N HCl. Products (+)-3 and 7 were filtered off by suction and recrystallized from ethanol.

General procedure for preparation of racemates (+)-4a-c and non-chiral analogues 8a-c. To a cooled (−5°C) and stirred solution of the appropriate derivative (+)-3 or 7 (0.06 mmol) in anhydrous THF (6 mL), Et$_3$N (7.21 mmol) was added. After 30 min, the mixture was allowed to warm up to 0°C, and ethyl chloroformate (2.27 mmol) was added. After 1 h, the appropriate arylamine (4.12 mmol) was added. The reaction was carried out at room temperature for 12 h. The mixture was then concentrated in vacuo, diluted with cold water (20–30 mL), and extracted with CH$_2$Cl$_2$ (3 × 15 mL). The solvent was evaporated to obtain the final compounds, which were purified by column chromatography using cyclohexane/ethyl acetate 2:1 (for compound (+)-4a), n-hexane/ethyl acetate 3:2 (for compounds (+)-4b,c), and cyclohexane/ethyl acetate 1:1 (for compounds 8a-c) as eluents.

Synthesis

General procedure for the mixture of the appropriate compound (+)-1 or 5

(7.41 mmol), K$_2$CO$_3$ (14.82 mmol), and ethyl bromoacetate (11.12 mmol) in CH$_2$CN (5 mL) was refluxed under stirring for 2-3 h. The mixture was then concentrated in vacuo, diluted with cold water, and extracted with CH$_2$Cl$_2$ (3 × 15 mL). The organic layer was evaporated in vacuo, and the final compounds (+)-2 and 6$^*$ were purified by column chromatography using cyclohexane/ethyl acetate 1:1 as eluent.

**X-ray Crystal Structure Analysis**

X-ray diffraction analysis of compounds S-(4)-4a,c and R-(4)-4b. X-ray analyses were carried out with a Goniometer Oxford Diffraction KM4 Xcalibur2. Graphite-monochromated Mo/Kα radiation (40 mA/40 KV) and a KM4 CCD/SAPPHIRE detector were used for cell parameter determination and data collection of S-(4)-4a and S-(4)-4c. Cu/Kα radiation (40 mA/40 KV), monochromated by an Oxford Diffraction Enhance ULTRA assembly, and an Oxford Diffraction Excillum PX Ultra CCD were used for cell parameter determination and data collection of R-(4)-4b.

The integrated intensities, measured using the w scan mode, were corrected for Lorentz and polarization effects. The structure was solved by direct methods of SIR200419 and refined using the full-matrix least squares on F² provided by SHELXL20. In all three compounds, the non-hydrogen atoms were refined anisotropically. Aromatic, methyl, methylene, and methinic hydrogens were assigned in calculated positions, only hydrogen on N-3 in S-(4)-4c was found in the Fourier synthesis; all hydrogen atoms were refined as isotropic.

The X-ray CIF file for each of the three structures has been deposited at the Cambridge Crystallographic Data Center and allocated with the deposition numbers CCDC 833484 [S-(4)-4a], CCDC 833486 [R-(4)-4b] and CCDC 833485 [S-(4)-4c] respectively. Copies of the data can be obtained, free of charge, from CCDC, 12 Union Road, Cambridge, CB2 1EZ UK (e-mail: deposit@ccdc.cam.ac.uk; internet: //www.ccdc.cam.ac.uk).

**Compound S-(4)-4a**. 4x(C_{19}H_{18}N_{3}O_{2}Br), M = 610.19, Triclinic, space group P1, a = 10.670(1), b = 12.244(1), c = 15.328(1) Å, V = 1832.0(3) Å³, Z = 1, D_{x} = 1.451, μ = 2.261 mm⁻¹, F(000) = 816, experiment T = 293 K.

Single crystals of S-(4)-4a were obtained by slow crystallization from EtOH. The asymmetric unit contained four independent molecules, as indicated in the molecular formula. 13926 reflections were collected with a 4.27 < θ < 29.41 range; 9827 were independent; the parameters were 902 and the final R index was 0.0518 for reflections having I > 2σ(I). There are four non equivalent molecules in the asymmetric unit. In PARST analysis, we found three significant intermolecular hydrogen bonds. They have the following parameters and show interactions along the a and b axes:

**Biological Assays**

**Cell Culture.** Human promyelocytic leukemia HL-60 cells stably transfected with FPR1 (HL-60-FPR1), FPR2 (HL-60-FPR2), or FPR3 (HL-60-FPR3) were cultured in RPMI 1640 medium supplemented with 10% heat-inactivated fetal calf serum, 10 mm HEPES, 100 μg/ml streptomycin, 100 U/ml penicillin, and G418 (1 mg/mL), as previously
Isolation of Human Neutrophils. Blood was collected from healthy donors in accordance with a protocol approved by the Institutional Review Board at Montana State University. Neutrophils were purified from the blood using dextran sedimentation, followed by Histopaque 1077 gradient separation and hypotonic lysis of red blood cells, as previously described. Isolated neutrophils were washed twice and resuspended in Hank's balanced-salt solution without Ca\textsuperscript{2+} and Mg\textsuperscript{2+} (HBSS). Neutrophil preparations were routinely >95% pure, as determined by light microscopy, and >98% viable, as determined by trypan blue exclusion.

Ca\textsuperscript{2+} Mobilization Assay. Changes in intracellular Ca\textsuperscript{2+} were measured with a FlexStation II scanning fluorometer using a FLIPR 3 calcium assay kit (Molecular Devices, Sunnyvale, CA, USA) for human neutrophils and HL-60 cells. All active compounds were evaluated in parent (wild-type) HL-60 cells for supporting that the agonists are inactive in non-transfected cells. Human neutrophils or HL-60 cells, suspended in HBSS containing 10 mm HEPES, were loaded with Fluor-4 AM dye (Invitrogen) (1.25 \( \mu \)g/mL final concentration) and incubated for 30 min in the dark at 37 \(^\circ\)C. After dye loading, the cells were washed with HBSS containing 10 mm HEPES and Ca\textsuperscript{2+} and Mg\textsuperscript{2+} (HBSS'), and aliquotted into the wells of a flat-bottomed, half-area-well black microtiter plates (2 \( \times \) 10\(^5\) cells/well). The compound source plate contained dilutions of test compounds in HBSS'. Changes in fluorescence were monitored (\( \lambda_{ex} = 485 \text{ nm}, \lambda_{em} = 538 \text{ nm} \)) every 5 sec for 240 sec at room temperature after automated addition of compounds. Maximum change in fluorescence, expressed in arbitrary units over baseline, was used to determine agonist response. Responses were normalized to the response induced by 5 nm fMLF (Sigma Chemical Co., St. Louis, MO, USA) for HL-60-FPR1 and neutrophils, or 5 nm WKYMVm (Calbiochem, San Diego, CA, USA) for HL-60-FPR2 and HL-60-FPR3 cells, which were assigned a value of 100%. Curve fitting (5–6 points) and calculation of median effective concentration values (EC\textsubscript{50}) were performed by nonlinear regression analysis of the dose–response curves generated using Prism 5 (GraphPad Software, Inc., San Diego, CA, USA).

RESULTS AND DISCUSSION

Synthesis

The already described (±)-1 and aromatic analogue 5, which was obtained from (±)-1 with bromine in acetic acid as the oxidizing agent (Scheme 1), were the key building blocks for synthesis of the final compounds (±)-4a-c and 8a-c. The alkylation under standard conditions with ethyl bromoacetate resulted in the racemate (±)-2 and the known non-chiral 6, from which the corresponding intermediates (±)-3 and 7 were obtained after alkaline hydrolysis. The final racemates (±)-4a-c and the non-chiral analogues 8a-c were prepared in good yields by treating the corresponding carboxylic acids (±)-3 and 7 with ethyl chloroformate in THF in the presence of triethylamine; the intermediate mixed anhydrides were not isolated but were directly transformed into the final amides using the appropriate aryl amine (Scheme 1). The pure compounds (±)-4a-c and 8a-c were crystallized from ethanol, and the results of H nmR, MS(ESI), and elemental analysis agreed with the assigned structure.

Chiral Resolution

In order to obtain complete resolution of the racemates (±)-4a-c, we performed an analytical chromatographic approach based on the screening of four different chiral stationary phases: Lux Amylose-2, Lux Cellulose-1, Lux Cellulose-2 and Lux Cellulose-3 (50 mm \( \times \) 4.6 mm I.D., 3 \( \mu \)m particle size). Different mobile phases were tested to determine the best combination of mobile and stationary phases for the resolution of racemates. The chromatographic results of the screening are reported in Table 1 as retention factor (\( k' \)), enantioselectivity (\( z \)) and resolution factors (R). Experimental data indicated that
the best resolutions (R > 1.5) were achieved using cellulose tris (3,5-dimethylphenylcarbamate) (Lux Cellulose-1) and n-Hex/IPA 90:10 and amylose tris (3,5-dimethylphenylcarbamate) (Lux Amylose-2) and MeCN/IPA 90:10. The other combinations of mobile/stationary phases tested were found to be unsuitable for resolving the samples tested.

Considering both systems (Lux Cellulose-1 with n-Hex/IPA 90:10 and Lux Amylose-2 with MeCN/IPA 90:10) showed a comparable chiral resolving ability, the criteria used to discriminate between methods was the solubility of the analytes in the respective mobile phases. Indeed, since the solubility of the racemates (±)-4a-c was poorer in n-Hex/IPA 90:10 than in MeCN/IPA 90:10, the latter method was chosen in order to increase the amount of analyte injected for each separation cycle and to reduce the times of separations. Once optimized, these analytical conditions were applied to the semipreparative system. Separations were performed on Lux Amylose-2 column (250 mm × 4.6 mm I.D., 5 μm) (Fig. 3) and were suitable to collect the required amounts of pure enantiomers (−)-4a-c and (+)-4a-c for biological studies. Finally, the fractions collected were analyzed in the analytical system using Lux Amylose-2 column and the aforementioned conditions to determine the enantiomeric excess (ee) of pure isomers, which resulted in ee values between 98.1% and 99.9% (Fig. 4).

**Configurational Assignment**

In order to establish absolute configuration of optically active compounds in the series, X-ray analysis was performed. Considering the difficulties in obtaining suitable crystals of all enantiomers, one isomer for each pair was processed for X-ray analysis, as reported for (−)-4a, (+)-4b and (−)-4c (Fig. 5) in the experimental section. Assignment of the absolute configurations at C5 was then unambiguously established for all of the enantiomers by a combination of crystallographic data, polarimetric analysis, and comparative elution order determined by chiral HPLC separations.

Among the three analyzed enantiomers, compound (−)-4a contains a bromine as a heavy atom that was useful in determining the exact configuration using the Flack parameter derived from X-ray analysis.24 For enantiomers (+)-4b and (−)-4c, the absolute configurations at C5 of the pyridazine ring could not be determined positively by using only Flack parameters, as these compounds don’t contain heavy atoms in their structures. Thus, these crystallographic results needed to be supported by a correlation with both polarimetric and chiral chromatographic analysis. Chiral HPLC and polarimetric analysis indicated that racemates (±)-4ac have same-sense chiral recognition mechanism and, in all cases, the first eluted enantiomer on Lux Amylose-2 column rotated the polarized light in the negative direction (Figs. 3 and 4). Since the chiral stationary phases are given just in one configuration, enantiomer elution order is a very important aspect in the study of enantiorecognition mechanisms.25 In a series of analogue compounds, such as in our case, the similarity of both skeleton and
substituents on a chiral center are the main determinant in retaining the same elution order for enantiomers having the same absolute configuration and, obviously, the same optical rotatory sign. X-ray data of (−)-4a univocally indicated an (S)-absolute configuration for this isomer. Thus, we could confirm that all enantiomers (−)-4ac were in the (S)-form and that the (R)-form could be assigned to the corresponding dextrorotatory isomers (+)-4ac. Absolute configurations were then unambiguously assigned as follows for the three enantiomeric pairs of the seres: S(−)-4ac and R(+)-4ac. Furthermore, the polarimetric and crystallographic data presented in this study may be useful to assign the absolute configuration of compounds having a similar structure to that of (±)-4ac.

**Pharmacology**

The final racemates (±)-4ac, the pure enantiomers S(−)-4ac/R(+)-4ac, and the non-chiral analogues 8ac were tested for their ability to induce intracellular Ca\(^{2+}\) flux in HL-60 cells transfected with FPR1, FPR2, or FPR3, in order to evaluate their ability to act as FPR agonists.\(^{20,27}\) As shown in Table 2, biological assays revealed that the bromo derivatives (±)-4a, S(−)-4a, R(+)-4a and 8a activated FPR1 and FPR2 with EC\(_{50}\) values in a similar micromolar range, whereas they were slightly more potent FPR2 agonists, with EC\(_{50}\) values between 7.0 and 10.7 μM. Moreover, enantiomers S(−)-4a and R(+)-4a also exhibited an appreciable agonistic activity for FPR3, with EC\(_{50}\) values in the low micromolar range (EC\(_{50}\) = 8.3 and 7.1 μM respectively). As reported in Table 2, all other compounds bearing a fluorine or a methylenedioxy side chain were inactive. To confirm specificity of the observed FPR agonist activity, the active compounds were also evaluated in WT cells (wild-type non transfected HL-60 cells) and were found to be inactive.

**TABLE 2. Analysis of FPR activation by racemates (±)-4a-c, pure enantiomers S(−)-4a-c/R(+)-4a-c, and non-chiral analogues 8a-c in HL-60 cells expressing human FPR1, FPR2, or FPR3**

\(^{a}\)N.A., no activity was observed (no response was observed during first 2 min after addition of compounds under investigation) considering the limits of efficacy >20% and EC\(_{50}\) < 50 μM. The EC\(_{50}\) values are presented as the mean of three independent experiments, in which median effective concentration values (EC\(_{50}\)) were determined by nonlinear regression analysis of the dose-response curves (5–6 points) generated using GraphPad Prism 5 with 95% confidential interval (p 0.05). Efficacy (in bracket) is expressed as percent of the response induced by 5 nM fMLF (FPR1) or 5 nM WKYMVm (FPR2 and FPR3).

**CONCLUSIONS**

Taken together, our data confirmed that the stereogenic center at C5 of the pyridazine ring plays only a marginal role in the activity and selectivity of the FPR agonists. On the other hand, the N-bromophenylacetamide moiety on the lactam nitrogen of the heterocyclic scaffold seems to play a major role in agonist activity, which is in agreement with previously reported agonists.\(^{7,11}\) Considering that pyridazine-based compounds represent good candidates for FPR-specific agonists, further studies are in progress to evaluate the influence of stereochemistry in other experimental in vitro models such as chemotaxis and neutrophils activation.

**ACKNOWLEDGMENTS**

This work was supported in part by National Institutes of Health grant GM103500, an equipment grant from the M.J. Murdock Charitable Trust, and the Montana State University Agricultural Experimental Station.
